Nonlinear Dynamics  (see also CAS Advanced Course)

(with strong emphasis on implementation)

The menu:

- Linear case (later generalization)

- Non-linear elements and power series, symplecticity (now non-linear elements)

- Linear maps (usually matrices) $\rightarrow$ non-linear maps

- Action-angle variables, invariants of motion and Liouville Theorem

- Thin lenses and symplectic integration
Nonlinear Dynamics  (see also CAS Advanced Course)

(with strong emphasis on implementation)

The ambition:

- Treat nonlinear dynamics without too many handwaving arguments

→ Find a formalism that can be "easily" extended to deal nonlinear dynamics !!

(extended means that it is the same for both cases)
Recommended Bibliography (and acknowledgement):

[AD] A. Dragt, Lie Methods for Nonlinear Dynamics with Applications to Accelerator Physics

For what follows one should (!) always use canonical variables!

In Cartesian coordinates: \( R = (X, P_X, Y, P_Y, Z, P_Z, t) \)

If the energy is constant (i.e. \( P_Z = \text{const.} \)), we use: \( (X, P_X, Y, P_Y, Z, t) \)

This system is rather inconvenient, what we want is the description of the particle in the neighbourhood of the reference orbit/trajectory:

\( R_d = (X, P_X, Y, P_Y, Z, t) \)

which are considered now the deviations from the reference and which are zero for a particle on the reference trajectory

**Very important: it is the reference not the design trajectory**!

(so far it is a straight line along the Z-direction)
The independent variable is usually the time \( t \) (Newton).

Problem: particles with different initial conditions generally require different times to pass through an element. Better to measure the progress using a longitudinal coordinate \( Z \).

We therefore replace time \( t \) by \( Z \) and eventually by \( s \) using:

\[ s = Z + ct \]

\[ R = (X, P_X, Y, P_Y, s) \]

\( s \) is the distance along reference path

Non-trivial: strictly speaking requires the Hamiltonian formalism

\( \rightarrow \) using \( s \) is Hamiltonian in disguise ...
For a "curved" trajectory, in general not circular, with a local radius of curvature $\rho(s)$ in the horizontal (X - Z plane), we transform to a new coordinate system $(x, y, s)$ (co-moving frame) with (see e.g. [AW]):

\[
X = (x + \rho) \cos \left( \frac{s}{\rho} \right) - \rho \quad \text{(needed tomorrow)}
\]

\[
Y = y
\]

\[
Z = (x + \rho) \sin \left( \frac{s}{\rho} \right)
\]

The new canonical momenta become:

\[
p_x = P_x \cos \left( \frac{s}{\rho} \right) + P_z \sin \left( \frac{s}{\rho} \right)
\]

\[
p_y = P_y
\]

\[
p_s = P_z \left( 1 + \frac{x}{\rho} \right) \cos \left( \frac{s}{\rho} \right) - P_x \left( 1 + \frac{x}{\rho} \right) \sin \left( \frac{s}{\rho} \right)
\]

finally for the transverse coordinates: $r = (x, p_x, y, p_y)$
Some clarification (again):

F.A.Q.: Phase Space \((x, p_x, \ldots)\) or Trace Space \((x, x', \ldots)\)

- Beam dynamics is strictly correct only with \((x, p_x, \ldots)\), but in general quantities cannot be measured easily
- Beam dynamics with \((x, x', \ldots)\) needs special precaution, but quantities much easier to measure or more relevant (e.g. crossing angle, bumps, ...)
- Some quantities are different (e.g. emittance)

Be aware of that when you do the calculations ...
Usual starting point: **Linear dynamics in synchrotrons**

Each element at position $s$ acts as a source of forces, i.e. we must write for the forces $K \rightarrow K(s)$ (so long harmonic oscillator ..... !)

To justify the Courant-Snyder ansatz:
linear (uncoupled !) optics in rings often introduced using 1D*) Hill type equation where $K(s)$ is assumed to be a **periodic** function in $s$:

$$
\frac{d^2 x(s)}{ds^2} + \left( a_0 + 2 \sum_{n=1}^{\infty} a_n \cdot \cos(2ns) \right) x(s) = 0 \quad \text{and} \quad K(s + C) = K(s)
$$

Solution of a **Boundary Value Problem** (rings !) must be periodic too !

Not applicable in the general case (e.g. Linacs, Beamlines, FFAG, Recirculators, ...), much better to treat it as an **Initial Value Problem**

*) What about 2D ??
First: For any linear, 1st order equation of the type
\[ \frac{dx(s)}{ds} = K(s) \cdot x(s) \quad \text{(and initial values at } s_0) \]
the solution can always be written as (Floquet, Hamilton, e.g. [AD]):
\[
\begin{align*}
  x(s) &= a \cdot x(s_0) + b \cdot x'(s_0) \\
  x'(s) &= c \cdot x(s_0) + d \cdot x'(s_0)
\end{align*}
\]
\[
\begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{s} = \begin{pmatrix}
  a & b \\
  c & d
\end{pmatrix} \begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{s_0}
\]
(now \( K(s) \) does not have to be periodic)

Second: The determinant of \( A \) is always 1

Third: No need for an "ansatz" (i.e. knowing the solution)

\[ \rightarrow \text{ Much better to use matrices for our linear systems from the start} \]
\[ \text{just have to know what is } A \text{ between the locations } s \text{ and } s_0 \]
Real life: adding nonlinear elements (e.g. magnetic fields)

Nonlinear elements can be described by polynomials of higher order:

\[
\frac{d^2 x(s)}{ds^2} + K(s) x(s) = \sum_{i,j \geq 0} p_{ij} x^i y^j
\]

Electromagnetic fields can be described with the multipole expansion:

\[
B_y + iB_x = \sum_{n=1} (b_n + i a_n) (x + iy)^{n-1}
\]

(in LHC need up to \( n = 20 \) !)

Equations of motions become (here horizontal plane):

\[
\frac{d^2 x(s)}{ds^2} + K(s) x(s) = \frac{F_x(x, y, s)}{v \times p} = - \frac{B_y(x, y, s)}{p}
\]

(Note: we have now coupling between the planes if \( i \neq 0 \) and \( j \neq 0 \) !!)
Some problems with this approach:

- It is rather hopeless to describe a complicated system
- It is totally hopeless to find a closed solution
- Perturbation treatment required, but does not always give satisfactory results and does not fully exploit potential of computing and numerical techniques
- Numerical methods create new problems, hopefully less important
- ...

Many concepts (more or less) valid in 1D become incorrect for 2D, hidden approximations (often inspired by the linear treatment) can lead to misconceptions and eventually permanent brain damage ..
The most reliable tools to study realistic models are simulations (e.g. tracking codes)

**Particle Tracking:**
.. a numerical solution of the (nonlinear) Initial Value Problem:
It is a "integrator" of the equation of motion
Vast amount of tracking codes available, many analysis tools available
(Examples: Lyapunov, Chirikov, chaos detection, frequency analysis, ...)

**Ambition:**
Find an approach to link simulations with theoretical analysis, would allow a better understanding of the physics in realistic machines

→ Based on finite maps i.e. discrete systems

Watch out for numerical problems !!
Look at the linear treatment first, then generalize to nonlinear theory

Linear optics was already treated in detail, I use the very basics to show the idea and demonstrate the transition

The procedure and formalism is identical

For consistency with some (classical) textbooks and other lectures I sometimes (where not critical) use $x, x', y, y'$ instead of $x, p_x, y, p_y$

Linear maps are usually written as matrices

Some simple examples (simplified, the full version later this week)
A drift space (one dimension only) of length $L$, starting at position $s$ and ending at $s + L$

The simplest description (1D, using $x, x'$) is (should be in 3D of course):

$$
\begin{pmatrix}
  x \\
  x' 
\end{pmatrix}_{s+L} =
\begin{pmatrix}
  1 & L \\
  0 & 1 
\end{pmatrix}
\circ
\begin{pmatrix}
  x \\
  x' 
\end{pmatrix}_s =
\begin{pmatrix}
  x + x' \cdot L \\
  x' 
\end{pmatrix}

This is only an approximation, something may go badly wrong, see later ... !
Focusing quadrupole of length $L$ and constant strength $k_1$ ($k_1 > 0$):

$$\begin{pmatrix} x \\ x' \end{pmatrix}_{s_2} = \begin{pmatrix} \cos(L \cdot \sqrt{k_1}) & \frac{1}{\sqrt{k_1}} \cdot \sin(L \cdot \sqrt{k_1}) \\ -\sqrt{k_1} \cdot \sin(L \cdot \sqrt{k_1}) & \cos(L \cdot \sqrt{k_1}) \end{pmatrix} \circ \begin{pmatrix} x \\ x' \end{pmatrix}_{s_1}$$

similar for a defocusing quadrupole, i.e. for $k_1 < 0$

(it is the solution of $\frac{d^2 x(s)}{d s^2} = K(s) x(s)$ when $K(s) = k_1 = const.$)

However: fundamental for the map approach

Can we get the maps:

1. For all elements, including nonlinear (e.g. sextupoles) where no solution exists?
2. From first principles (i.e. fields), without reference to their use?
(a particle does not know what the element is (supposed) to do?)
Starting from a position $s_0$ and combining all matrices to get the matrix to position $s_0 + L$ (shown for 1D only):

$$
\begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{s_0 + L} = M_N \circ M_{N-1} \circ ... \circ M_1 \circ \underbrace{M(s_0,L)}_{M_{(s_0,L)}} \begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{s_0}
$$

For a ring with circumference $C$ we get the One-Turn-Matrix (OTM) at $s_0$

$$
\begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{s_0 + C} = \begin{pmatrix}
  m_{11} & m_{12} \\
  m_{21} & m_{22}
\end{pmatrix} \circ \underbrace{M_{(s_0,C)}}_{M_{OTM}} \begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{s_0}
$$

Without proof (trust me for a few minutes), the scalar product:

$$
\begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{s_0} \cdot M_{OTM} \cdot \begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{s_0} = \text{const.} = J
$$

is a constant of the motion: invariant of the One-Turn-Map $M_{OTM}$
Next: matrices can be transformed into **Normal Forms**

we try to find a (invertible) transformation $A$ such that (called "similarity transformation"):

$$AMA^{-1} = R \quad \text{(or: \quad A^{-1}RA = M)}$$

- The matrix $R$ is:
  - A "Normal Form", (or at least a very simplified form of the matrix)
  - Example (most important case): $R$ becomes a pure rotation

- The matrix $R$ describes the same dynamics as $M$, but:
  - All coordinates are transformed by $A$
  - This transformation $A$ "analyses" the complexity of the motion, it contains the structure of the phase space
Transformation to Normal Form (pictorially)

\[ M = \mathcal{A} \circ R \circ \mathcal{A}^{-1} \quad \text{or} \quad R = \mathcal{A}^{-1} \circ M \circ \mathcal{A} \]

Motion on an ellipse becomes motion on a circle (i.e. a rotation): \( R \) is the "simple" part of the map - shape is "dumped" into \( \mathcal{A} \)

How to get that (i.e. \( \mathcal{A} \)) ? Remember lectures on Linear Algebra (Eigenvectors, Eigenvalues ...), see also backup slides
We find the two components of the original map:

\[
\mathcal{H} = \begin{pmatrix}
\frac{\sqrt{\beta(s_0)}}{\sqrt{\beta(s_0)}} & 0 \\
-\frac{\alpha(s_0)}{\sqrt{\beta(s_0)}} & 1/\sqrt{\beta(s_0)}
\end{pmatrix}
\quad \text{and} \quad
\mathcal{R} = \begin{pmatrix}
\cos(\mu_x) & \sin(\mu_x) \\
-\sin(\mu_x) & \cos(\mu_x)
\end{pmatrix}
\]

The Normal Form transformation gives plenty of information:

- We have stable oscillations when the eigenvalues \(\mu_x\) (and \(\mu_y\) etc.) are real, (forget about the \(\text{Tr}(\mathcal{M}) \leq 2\) business). This concept is valid also for 2D or any complicated systems, e.g. coherent motion with \(6000 \times 6000\) matrices etc: many modes!
- \(\mu_x\) is the "tune" \(Q_x \cdot 2\pi\) (now we can talk about phase advance !)
- \(\beta, \alpha, ...\) are the optical parameters and describe the ellipse
- The closed orbit (an invariant, identical coordinates after one turn !):

\[
\mathcal{M}_{OTM} \circ (x, x')_c \equiv (x, x')_c
\]
Note 1:

- The **only** assumption was that particles make more than one turn !!!
- Matrices $R$ and $M$ are called **similar** (i.e. have the same eigenvalues) (to be equivalent is not sufficient !)

Note 2:

in 2 dimensions the normal form is a $4 \times 4$ matrix:

$$
\mathcal{R}^{2D} = \begin{pmatrix}
\cos(\mu_x) & \sin(\mu_x) & 0 & 0 \\
-\sin(\mu_x) & \cos(\mu_x) & 0 & 0 \\
0 & 0 & \cos(\mu_y) & \sin(\mu_y) \\
0 & 0 & -\sin(\mu_y) & \cos(\mu_y)
\end{pmatrix} = \begin{pmatrix}
A & 0 \\
0 & B
\end{pmatrix}
$$

What if the two planes (oscillators) are linearly coupled ?
Assume a one-turn-matrix in 2D ($4 \times 4$ matrix):

$$R = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$$

coupling!

$$T = \begin{pmatrix} M & n \\ m & N \end{pmatrix}$$

M,m,N,n are 2-by-2 block matrices.

In case of coupling: $m \neq 0, n \neq 0$ we can try to transform as:

$$T = \begin{pmatrix} M & n \\ m & N \end{pmatrix} = VR'V^{-1}$$

with (same procedure as before, find the simple case):

$$R' = \begin{pmatrix} A' & 0 \\ 0 & B' \end{pmatrix}$$

and

$$V = \begin{pmatrix} \gamma I & C \\ -C' & \gamma I \end{pmatrix}$$
A short comparison of the different approaches (not rigorous)

Classical perturbation method:
- Transform/expand solution in terms of distortion parameter
- Analytical/symbolic expression for the solution
- Solution is approximate (eigenvalues inexact, not always useful)

Map/Normal Form approach:
- Transform Differential Equation in terms of distortion parameter (Normal Form) to get an equation that can be solved
- No symbolic expression for the solution
- Requires some approximation of the model
- Procedure to get solutions/eigenvalues is exact

Using the map/Normal Form approach we get an exact solution at the expense of giving up a closed analytical form for the solution
Impact on a key concept:

A central question in physics (accelerator theory) is to find, understand and quantify **invariants**:

A property of a system that is unchanged, i.e. conserved as the system evolves (typical examples are: energy, momentum, angular momentum, charge, invariant mass, speed of light, ..)

Given a map $\mathcal{M}$ we look for $\zeta$ with

$$\mathcal{M} \zeta = \zeta$$

e.g. Special Relativity is all about invariants ("mechanics", electrodynamics, ..)
More appropriate for studies: using Action - Angle variables

Once the particles "travel" on a circle (i.e. always !), the motion is better described by the canonical variables action $J_x$ and angle $\Psi_x$: 

\[
x = \sqrt{2J_x} \beta_x \cos(\Psi_x)
\]

\[
p_x = -\sqrt{\frac{2J_x}{\beta_x}} (\sin(\Psi_x) + \alpha_x \cos(\Psi_x))
\]

\[
J_x = \frac{1}{2} (\gamma_x x^2 + 2\alpha_x xp_x + \beta_x p_x^2) \quad (*)
\]

Angular position along the ring $\Psi$ becomes the independent variable !

The trajectory of a particle is now independent of the position $s$ !

Constant Radius $\sqrt{2J}$ defines action $J$ (invariant of motion)

*) Never call that "emittance", this is fraudulent and brain clobbering !
Interlude: If we have many particles, action is related to beam emittance (this is valid also for sources, electrons, linacs and beam lines, and non-Gaussian beams:

If we can measure $\langle x^2 \rangle$, $\langle p_x^2 \rangle$ and $\langle x p_x \rangle$ of a beam, and define a beam emittance $\epsilon_x$ (see e.g. [AW, AC2], also CERN convention):

\[
\epsilon_x = \langle J_x \rangle
\]

this means:

\[
\epsilon_x = \sqrt{\langle x^2 \rangle \langle p_x^2 \rangle - \langle x p_x \rangle^2}
\]

We can use action-angle variables defined before as:

\[
x = \sqrt{2J_x\beta_x} \cos(\Psi_x) \quad p_x = -\sqrt{\frac{2J_x}{\beta_x}} (\sin(\Psi_x) + \alpha_x \cos(\Psi_x))
\]

and from above we get ($\Psi$ disappears by the averaging)

\[
\langle x^2 \rangle = \beta_x \epsilon_x, \quad \langle x p_x \rangle = -\alpha_x \epsilon_x, \quad \langle p_x^2 \rangle = \gamma_x \epsilon_x
\]
Since other definitions often refer to the treatment by Courant and Snyder, here a quote from Courant himself:

"The invariant $J$ is simply related to the area enclosed by the ellipse:

\[
\text{Area enclosed} = 2\pi J.
\]

In accelerator and storage ring terminology there is a quantity called the emittance which is closely related to this invariant. The emittance, however, is a property of a distribution of particles, not a single particle. Consider a Gaussian distribution in amplitudes. Then the (rms) emittance, $\epsilon$, is given by:

\[
(x_{\text{rms}})^2 = \beta_x(s) \cdot \epsilon_x.
\]

In terms of the action variable, $J$, this can be rewritten

\[
\epsilon_x = \langle J \rangle.
\]

where the bracket indicates an average over the distribution in $J$.

Note: this is also the CERN and CAS convention..."
Introducing nonlinear elements: various types of nonlinear maps

Choice depends on the application, some examples:

- Taylor (Power) maps
- Lie transformations
- Truncated Power Series Algebra (TPSA), can generate maps from tracking (see lectures by Etienne Forest)

Not all maps are allowed!

- Key concept: Symplecticity (again) most relevant for rings!

Linear first..
A symplectic matrix $\mathcal{M}$ has to fulfil the condition:

$$\mathcal{M}^T \cdot S \cdot \mathcal{M} = S$$

with

$$S = \begin{pmatrix}
0 & 1 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0
\end{pmatrix}$$

\[
\lim_{n \to \infty} \mathcal{M}^n = \text{finite} \implies \text{requires } \det \mathcal{M} = 1^*)
\]

1. $\mathcal{M}$ is area preserving $(x, p)$ and $J$ is an invariant:

$$\mathcal{M} J = J$$

2. All eigenvalues of $\mathcal{M}$ are non-zero and it is invertible

3. Products of symplectic matrices are symplectic

*) (But note: $\det \mathcal{M} = 1$ alone is not sufficient, except in 1D)
Introducing nonlinear elements (e.g. 2nd order)

Effect of a sextupole-like element with strength $k_2$ is (normal component):

$$
\begin{pmatrix}
  x \\
  x' \\
  y \\
  y'
\end{pmatrix}_{s_2} =
\begin{pmatrix}
  x \\
  x' \\
  y \\
  y'
\end{pmatrix}_{s_1} +
\begin{pmatrix}
  0 \\
  -\frac{1}{2} k_2 L \cdot (x_{s_1}^2 - y_{s_1}^2) \\
  0 \\
  \frac{1}{2} k_2 L \cdot (x_{s_1} \cdot y_{s_1})
\end{pmatrix}
$$

→ Amplitudes appear as second power

→ (Normally) Cannot be written as a matrix
We need something like (here for $x$-coordinate), i.e. **Power Series**:

\[
x_{new} = \begin{cases} 
\text{matrix part (power 1)} \\
R_{11} \cdot x + R_{12} \cdot x' + R_{21} \cdot y + R_{22} \cdot y' + \\
\text{sextupole part (power 2)} \\
+ T_{111} \cdot x^2 + T_{112} \cdot xx' + T_{122} \cdot x'^2 + T_{113} \cdot xy + T_{114} \cdot xy' + \ldots \\
\text{octupole part (power 3)} \\
+ U_{1111} \cdot x^3 + U_{1112} \cdot x^2 x' + \ldots \\
+ \ldots 
\end{cases}
\]

and the equivalent for $x'_{new}, y_{new}, y'_{new}$ and higher orders

**Note:** for sextupoles and higher we have coupling terms $x^n y^m$, etc.
Normally, because one could write it as (1D, horizontal plane only):

\[
\begin{pmatrix}
  x \\
  x'
\end{pmatrix}_{\text{new}} =
\begin{pmatrix}
  R_{11} & R_{12} & T_{111} & T_{112} & T_{122} \\
  R_{21} & R_{22} & T_{211} & T_{212} & T_{222}
\end{pmatrix} \circ
\begin{pmatrix}
  x \\
  x' \\
  x^2 \\
  x'x \\
  x'^2
\end{pmatrix}
\]

Just a fake, looks good but does not win anything ..

Easier to implement as (here up to 3rd order):

\[
z_{j}^{\text{new}} = \sum_{k=1}^{6} R_{jk}z_k + \sum_{k=1}^{6} \sum_{l=1}^{6} T_{jkl}z_k z_l + \sum_{k=1}^{6} \sum_{l=1}^{6} \sum_{m=1}^{6} U_{jklm}z_k z_l z_m \quad \text{for} \quad j = 1..6
\]
Explicit map (2D) for a sextupole with length \( L \) and strength \( k_2 \):

\[
\begin{align*}
x_2 &= x_1 + Lx'_1 - k_2 \left( \frac{L^2}{4} (x_1^2 - y_1^2) + \frac{L^3}{12} (x_1x'_1 - y_1y'_1) + \frac{L^4}{24} (x_1'^2 - y_1'^2) \right) \\
x'_2 &= x'_1 - k_2 \left( \frac{L}{2} (x_1^2 - y_1^2) + \frac{L^2}{4} (x_1x'_1 - y_1y'_1) + \frac{L^3}{6} (x_1'^2 - y_1'^2) \right) \\
y_2 &= y_1 + Ly'_1 + k_2 \left( \frac{L^2}{4} x_1y_1 + \frac{L^3}{12} (x_1y'_1 + y_1x'_1) + \frac{L^4}{24} (x_1'y'_1) \right) \\
y'_2 &= y'_1 + k_2 \left( \frac{L}{2} x_1y_1 + \frac{L^2}{4} (x_1y'_1 + y_1x'_1) + \frac{L^3}{6} (x_1'y'_1) \right)
\end{align*}
\]

- Can this be used in this form?

- This is not a matrix - what about the "symplectic" condition?

How to test it?

(if bored: find \( T_{234}, T_{324} \ ... \))
It is the associated Jacobian matrix $\mathcal{J}$ (all 1st order partial derivatives) which must fulfil the symplycticity condition:

$$
\mathcal{J}_{ik} = \frac{\partial z_i^j}{\partial z_k^k} \quad \text{(e.g. } \mathcal{J}_{xy} = \frac{\partial x_2}{\partial y_1})
$$

$\mathcal{J}$ must fulfil: $\mathcal{J}^T \cdot S \cdot \mathcal{J} = S$

The coordinate $z$ and the phase space dimension can be very high order: (number of particles) $\cdot$ (number of degrees of freedom)

(LHC $\approx 10^{15}$, in most of my examples $n = 4$)

$$
z_2^n = M z_1^n
$$

... an interesting consequence $\rightarrow$
Transformation of the occupied phase space

\[ V_2 = \int_{V_2} d^n z_2 = \int_{V_1} \left| \frac{\partial z_2}{\partial z_1} \right| d^n z_1 = \int_{V_1} |\mathcal{M}| d^n z_1 = \int_{V_1} d^n z_1 = V_1 \]

Under symplectic transformations phase space volume is conserved !!

This is Liouville’s theorem !!

(not to be mistaken for Poincare invariant: \[ \int p \cdot dq = \text{const.} \] )
There is also a problem:

\[ \mathcal{J}_{ik} = \frac{\partial z_2^i}{\partial z_1^k} \quad \left( \text{e.g. } \mathcal{J}_{xy} = \frac{\partial x_2}{\partial y_1} \right) \]

\[ \mathcal{J} \text{ must fulfil: } \mathcal{J}^T \cdot S \cdot \mathcal{J} = S \]

In general: \( \mathcal{J}_{ik} \neq \text{const} \) (i.e. depend on \( x_1, x'_1, \ldots \))

Confusing ?? o.k. \( \rightarrow \) example sextupoles
\[x_2 = x_1 + Lx'_1 - k_2 \left( \frac{L^2}{4} (x_1^2 - y_1^2) + \frac{L^3}{12} (x_1 x'_1 - y_1 y'_1) + \frac{L^4}{24} (x'_1 - y_1^2) \right)\]

\[x'_2 = x'_1 - k_2 \left( \frac{L}{2} (x_1^2 - y_1^2) + \frac{L^2}{4} (x_1 x'_1 - y_1 y'_1) + \frac{L^3}{6} (x'_1 - y_1^2) \right)\]

\[y_2 = y_1 + Ly'_1 + k_2 \left( \frac{L^2}{4} x_1 y_1 + \frac{L^3}{12} (x_1 y'_1 + y_1 x'_1) + \frac{L^4}{24} (x'_1 y'_1) \right)\]

\[y'_2 = y'_1 + k_2 \left( \frac{L}{2} x_1 y_1 + \frac{L^2}{4} (x_1 y'_1 + y_1 x'_1) + \frac{L^3}{6} (x'_1 y'_1) \right)\]

\[
\mathcal{J}_{ik} = \begin{pmatrix}
\frac{\partial x_2}{\partial x_1} & \frac{\partial x_2}{\partial x'_1} & \frac{\partial x_2}{\partial x'_2} & \frac{\partial x_2}{\partial x'_1} \\
\frac{\partial x'_2}{\partial x_1} & \frac{\partial x'_2}{\partial x'_1} & \frac{\partial x'_2}{\partial x'_2} & \frac{\partial x'_2}{\partial x'_1} \\
\frac{\partial y_2}{\partial x_1} & \frac{\partial y_2}{\partial x'_1} & \frac{\partial y_2}{\partial y_1} & \frac{\partial y_2}{\partial y'_1} \\
\frac{\partial y_2}{\partial x_1} & \frac{\partial y_2}{\partial x'_1} & \frac{\partial y_2}{\partial y_1} & \frac{\partial y_2}{\partial y'_1} \\
\frac{\partial y'_2}{\partial x_1} & \frac{\partial y'_2}{\partial x'_1} & \frac{\partial y'_2}{\partial y_1} & \frac{\partial y'_2}{\partial y'_1} \\
\frac{\partial y'_2}{\partial x_1} & \frac{\partial y'_2}{\partial x'_1} & \frac{\partial y'_2}{\partial y_1} & \frac{\partial y'_2}{\partial y'_1}
\end{pmatrix}
\]

\[
\begin{pmatrix}
1 & L & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & L \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

For \(k_2 \neq 0\) coefficients depend on initial values, e.g.:

\[
\frac{\partial y_2}{\partial y_1} = 1 + k_2 \left( \frac{L^2}{4} x_1 y_1 + \frac{L^3}{12} (x_1 y'_1 + y_1 x'_1) + \frac{L^4}{24} (x'_1 y'_1) \right)
\]

Power series are not symplectic, cannot be used.
\[
\begin{align*}
x_2 &= x_1 + Lx'_1 - k_2 \left( \frac{L^2}{4}(x_1^2 - y_1^2) + \frac{L^3}{12}(x_1 x'_1 - y_1 y'_1) + \frac{L^4}{24}(x_1^2 - y_1^2) \right) \\
x'_2 &= x'_1 - k_2 \left( \frac{L}{2}(x_1^2 - y_1^2) + \frac{L^2}{4}(x_1 x'_1 - y_1 y'_1) + \frac{L^3}{6}(x_1^2 - y_1^2) \right) \\
y_2 &= y_1 + Ly'_1 + k_2 \left( \frac{L^2}{4}x_1y_1 + \frac{L^3}{12}(x_1 y'_1 + y_1 x'_1) + \frac{L^4}{24}(x_1 y'_1) \right) \\
y'_2 &= y'_1 + k_2 \left( \frac{L}{2}x_1y_1 + \frac{L^2}{4}(x_1 y'_1 + y_1 x'_1) + \frac{L^3}{6}(x_1 y'_1) \right)
\end{align*}
\]

\[
J_{ik} = \begin{pmatrix}
\frac{\partial x_2}{\partial x_1} & \frac{\partial x_2}{\partial x'_1} & \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y'_1} \\
\frac{\partial x'_2}{\partial x_1} & \frac{\partial x'_2}{\partial x'_1} & \frac{\partial x'_2}{\partial y_1} & \frac{\partial x'_2}{\partial y'_1} \\
\frac{\partial y_2}{\partial x_1} & \frac{\partial y_2}{\partial x'_1} & \frac{\partial y_2}{\partial y_1} & \frac{\partial y_2}{\partial y'_1} \\
\frac{\partial y'_2}{\partial x_1} & \frac{\partial y'_2}{\partial x'_1} & \frac{\partial y'_2}{\partial y_1} & \frac{\partial y'_2}{\partial y'_1}
\end{pmatrix}
\]

For \( k_2 \neq 0 \) coefficients depend on initial values, e.g.:

\[
\frac{\partial y_2}{\partial y_1} = 1 + k_2 \left( \frac{L^2}{4}x_1 + \frac{L^3}{12}x'_1 \right) \quad \text{Power series are not symplectic, cannot be used}
\]
Directly using finite power series maps is ruled out ...

Small error for small $L$, no error for $L = 0$!

Accelerator physicists love **Zero length elements:**

engineers don’t, they are technically difficult

**Thick "magnet":**

Length and Strength specified for computation

Example sextupole: $L$ and $k_2$

**Thin "magnet":**

let the length go to zero, but keep **Field Integral** finite ($L$ and $k_n$ are not specified separately):

Example sextupole: $L \cdot k_2$
The "momentum" $x'$ receives an amplitude dependent deflection, "kick" $x' \rightarrow x' + \Delta x'$

$$\Delta x' = f(x) \quad \text{(polynomials of some - possibly high - order)}$$

Always symplectic: no change of amplitude inside the element, no dependence on initial angle
Can we approximate a thick element by one or more thin element(s) ?

Yes, when the length is small or does not matter

Symplecticity o.k.

What about accuracy, what have we lost ??

Demonstrate with some simple examples

(What follows is valid for all elements and provides the tools !!!)
Check out a quadrupole:

- Start with "exact") map, compare with thin quadrupole

\[
M_{s\rightarrow s+L} = \begin{pmatrix}
\cos(L \cdot \sqrt{K}) & \frac{1}{\sqrt{K}} \cdot \sin(L \cdot \sqrt{K}) \\
-\sqrt{K} \cdot \sin(L \cdot \sqrt{K}) & \cos(L \cdot \sqrt{K})
\end{pmatrix}
\]

- Thick to thin: make \( L \) smaller and smaller, this permits:

Taylor/power expansion (of \( \sin \) and \( \cos \)) in "small" length \( L \):

\[
M = L^0 \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + L^1 \cdot \begin{pmatrix} 0 & 1 \\ -K & 0 \end{pmatrix} + L^2 \cdot \begin{pmatrix} -\frac{K}{2} & 0 \\ 0 & -\frac{K}{2} \end{pmatrix} + \ldots
\]

Keep up to first order term in $L$  
(contribution with $L^2$ is small)

\[ M = L^0 \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + L^1 \cdot \begin{pmatrix} 0 & 1 \\ -K & 0 \end{pmatrix} \]

\[ M = \begin{pmatrix} 1 & L \\ -K \cdot L & 1 \end{pmatrix} + O(L^2) \]

Precise to first order $O(L^1)$

\[ \det M = (1 + KL^2) \neq 1, \text{ non-symplectic !} \]
A possible remedy out of the blue:

If we add a term $-KL^2$ the matrix becomes symplectic:

$$
\mathcal{M} = \begin{pmatrix}
1 & L \\
-K \cdot L & 1-KL^2
\end{pmatrix}
$$

$$
det \mathcal{M} = (1 - KL^2 + KL^2) = 1
$$

- The model is exact and symplecticity is recovered, the (magnet) model is slightly inaccurate (approximate, remember yesterday)

- We have not damaged the accuracy too much, the original truncated matrix is inaccurate to order $O(L^2)$ anyway ...
Carry on:

Keep up to second order term in $L$

$$\mathcal{M} = \begin{pmatrix} 1 - \frac{1}{2}KL^2 & L \\ -K \cdot L & 1 - \frac{1}{2}KL^2 \end{pmatrix} + O(L^3)$$

- Precise to second order $O(L^2)$
- More accurate than before, but again not symplectic

Make it symplectic by adding $-\frac{1}{4}KL^3$

$$\mathcal{M} = \begin{pmatrix} 1 - \frac{1}{2}KL^2 & L - \frac{1}{4}KL^3 \\ -K \cdot L & 1 - \frac{1}{2}KL^2 \end{pmatrix} + O(L^3)$$

This model is more accurate and symplectic, error is of higher order than before
For many kicks: every "kick" is symplectic

Is there a physical picture behind the approximations?

Yes \(\rightarrow\) geometry of thin lens kicks ...

A thick element we should split into one or more thin elements with drifts between them, (cut and shrink) e.g.:
Thick quadrupole $\rightarrow$ thin quadrupoles $\rightarrow$ "kicks"

Represented by one or more "thin" lenses (kicks)

How many and where?

Which is a good strategy? $\rightarrow$ accuracy and simplicity

Be reasonable, no need to have a longitudinal position precise to $10^{-15}$ m.. (it is a small step for a man but a giant leap to nonsense)
One thin quadrupole "kick" and one drift combined

\[
M_{\text{drift + kick}} = \begin{pmatrix}
1 & 0 \\
-K \cdot L & 1
\end{pmatrix}
\begin{pmatrix}
1 & L \\
0 & 1
\end{pmatrix}
= \begin{pmatrix}
1 & L \\
-K \cdot L & 1 - KL^2
\end{pmatrix}
\]

Reminder: product of symplectic matrices is symplectic

Resembles our "symplectification" of order O(1)
Option 2

One thin quadrupole "kick" between two drifts of half length

\[ M = \begin{pmatrix} 1 & \frac{1}{2}L \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -K \cdot L & 1 \end{pmatrix} \begin{pmatrix} 1 & \frac{1}{2}L \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 - \frac{1}{2}KL^2 & L - \frac{1}{4}KL^3 \\ -K \cdot L & 1 - \frac{1}{2}KL^2 \end{pmatrix} \]  

Resembles more accurate "symplectification" of order O(2)
Accuracy of thin lenses

- One kick at the end (or beginning):
  - Error (inaccuracy) of second order $O(L^2)$

- One kick in the centre:
  - Error (inaccuracy) of third order $O(L^3)$

It is very relevant how to apply thin lenses!

If you describe a quadrupole like:

$$\begin{pmatrix} 1 & 0 \\ \frac{1}{f} & 1 \end{pmatrix}$$

The aim should be to be precise and fast (and simple to implement)

Check whether the approximation is valid for you ...
Increase the number of "kicks": What about these options?

or:

Home exercises: Are they symplectic?
Can one do better? Try a model with 3 kicks:

- Kicks $c_1$, $c_2$, $c_3$ (allow different strength)
- Drifts $d_1$, $d_2$, $d_3$, $d_4$ (allow any position of the kicks, but NO need to be accurate to attometres)

To get best accuracy (i.e. deviation from exact solution):

You have 7 free parameters to minimize deviation:
The optimization gives us: (for the derivation, e.g. [AC1])

\[ a \cdot L \quad \alpha \cdot K \quad L \quad \alpha \cdot K \quad L \quad a \cdot L \]

\[ b \cdot L \quad b \cdot L \quad \beta \cdot K \quad L \]

with:

\[
\begin{align*}
    a &= \frac{1}{2} \cdot \frac{1}{2 - 2^{1/3}}, \\
    b &= \frac{1 - 2^{1/3}}{2} \cdot \frac{1}{2 - 2^{1/3}}, \\
    \alpha &= \frac{1}{2 - 2^{1/3}}, \\
    \beta &= -\frac{2^{1/3}}{2 - 2^{1/3}} \cdot \frac{1}{2 - 2^{1/3}}
\end{align*}
\]

We have a \( O(4) \) integrator ... (without proof)

Watch out: it is \(-2^{1/3}\) and not \((-2^{1/3})\) (remember yesterday !)
Resulting matrix $\mathcal{M}$ (from the 7 matrices: 4 drifts, 3 kicks) becomes:

$$
\mathcal{M}(O4) = \begin{pmatrix}
1 - \frac{1}{2} k^2 L^2 + \frac{1}{24} k^4 L^4 & L - \frac{1}{6} k^2 L^3 + \frac{1-2^{1/3}}{24(2-2^{1/3})^2} k^4 L^5 \\
+ \frac{2^{1/3}}{48(2-2^{1/3})^3} k^6 L^6 & + \frac{2^{1/3}}{96(2-2^{1/3})^4} k^6 L^7 \\
-k^2 L + \frac{1}{6} k^4 L^3 & 1 - \frac{1}{2} k^2 L^2 + \frac{1}{24} k^4 L^4 \\
+ \frac{2^{1/3}}{24(2-2^{1/3})^2} k^6 L^5 & + \frac{2^{1/3}}{48(2-2^{1/3})^3} k^6 L^6
\end{pmatrix}
$$

For the ambitious - Prove that it is symplectic

(MATHEMATICA® is really a good friend ...)

Why all that ? (answer in a few minutes)
What we do is a **Symplectic Integration**

From a lower order integration scheme (1 kick), construct higher order scheme:

$$\hat{O}(2) \Rightarrow \hat{O}(4) \Rightarrow \hat{O}(6) \Rightarrow ...$$

Formally (for the formulation of $S_k$ see later):

From a 2nd order scheme (1 kick) $S_2$ we construct a 4th order scheme (3 kicks = 3 x 1 kick) like:

$$S_4 = S_2(x_1) \circ S_2(x_0) \circ S_2(x_1) \quad \text{with scaling coefficients:}$$

$$x_0 = \frac{-2^{1/3}}{2 - 2^{1/3}} \quad x_1 = \frac{1}{2 - 2^{1/3}}$$
Can be considered an iterative scheme (see e.g. H. Yoshida, 1990, E. Forest, 1998):

If $S_{2k}$ is a symmetric integrator of order $2k$, then:

$$S_{2k+2} = S_{2k}(x_1) \circ S_{2k}(x_0) \circ S_{2k}(x_1)$$

with:

$$x_0 = \frac{-2^{k+1}\sqrt{2}}{2 - 2^{k+1}\sqrt{2}} \quad x_1 = \frac{1}{2 - 2^{k+1}\sqrt{2}}$$

Higher order integrators can be obtained in a similar way:

$$S_{2k} \rightarrow S_{2k+2} \rightarrow S_{2k+4} \rightarrow S_{2k+6} \rightarrow \ldots$$

Stop at the desired order, rather simple to implement on a computer (with paper and pencil makes you a lunatic)
Example: From a 4th order to 6th order

\[ S_6 = S_4(x_1) \circ S_4(x_0) \circ S_4(x_1) \]

Replace each kick of a 4th order integrator by a 4th order integrator, using the same scaling factors.

We get 3 times 4th order with 3 kicks each, we have the 9 kick, 6th order integrator mentioned earlier.
Integrator of order 2 ➞ 4

Replace kick by 4th order integrator
Integrator of order 4 $\rightarrow$ 6 - step by step

Replace each kick by 4th order integrator
Integrator of order 4 $\Rightarrow$ 6 - step by step

Replace each kick by 4th order integrator
Integrator of order 4 $\Rightarrow 6$ - step by step

- Replace each kick by 4th order integrator, requires 9 kicks
- We have 3 interleaved 4th order integrators (compute $M(O6)$), repeat the procedure to go to higher orders
We have used a linear map (quadrupole) to demonstrate the integration

Can that be applied for other maps (solenoids, higher order, nonlinear maps) ?

Yes !!

One gets the same coefficients !

Proof and systematic (and easy) extension in the form of Lie operators (see tomorrow)

Without proof: best possible accuracy for thin lenses (be smart: a scheme with more thin lenses may be less precise, even if the position is as accurate as attometres !)
To remember:

Given a truncated Power map we construct a symplectic map whose lower order terms agree with the exact non-symplectic Power expansion and whose higher order (neglected) terms are small.

Key question:

How can we say that the neglected terms do not exceed a tolerable limit?
What is the point ???

Phase space ellipse - quadrupole exact solution
**Quadrupole non-symplectic solution** $L^1$

Non-symplecticity: particles spiral towards outside, artifact of approximation (of the algorithm)
Quadrupole symplectic $O(L^1)$ solution

Exact quadrupole versus thin lens approximation

Exact map and symplectic map $O(1)$

symplectic, solution order $O(L^1)$, but visible inaccuracy
Quadrupole symplectic $O(L^2)$ solution

symplectic, solution order $O(L^2)$, but good accuracy
Quantitatively: Accuracy of (nonlinear) thin lenses

Nonlinear elements are usually thin (thinner than dipoles, quadrupoles ...)

- Dipoles: $\approx 14.3 \text{ m}$
- Quadrupole: $\approx 2 - 5 \text{ m}$
- Sextupoles, Octupoles: $\approx 0.30 \text{ m}$
- Decapole: $\approx 0.07 \text{ m}$

Assume a kick from a general function of $x$:
deflection : $\Delta x' = f(x)$

e.g. quadrupole $f(x) = k \cdot x^1$

e.g. sextupole $f(x) = k \cdot x^2$

e.g. octupole $f(x) = k \cdot x^3$

→ Can try our simplest thin lens approximation O(2) first ...
Drift - Kick - Drift

\[ \Delta x' = f(x) \]

\[ \begin{array}{c}
\begin{bmatrix}
x \\
x'
\end{bmatrix}
\end{array} =
\begin{bmatrix}
1 & \frac{L}{2} \\
0 & 1
\end{bmatrix}
\begin{array}{c}
\begin{bmatrix}
x_0 \\
x'_0
\end{bmatrix}
\end{array}
\]

1.\textit{Step} \quad \begin{bmatrix} x \\ x' \end{bmatrix}_{s_1+L/2} = \begin{bmatrix} x \\ x' + \Delta x' \end{bmatrix}_{s_1+L/2} = \begin{bmatrix} x \\ x' + f(x) \end{bmatrix}_{s_1+L/2}

2.\textit{Step} \quad \begin{bmatrix} x \\ x' \end{bmatrix}_{s_1+L/2} = \begin{array}{c}
\begin{bmatrix}
x \\
x'
\end{bmatrix}
\end{array} =
\begin{bmatrix}
1 & \frac{L}{2} \\
0 & 1
\end{bmatrix}
\begin{array}{c}
\begin{bmatrix}
x \\
x'
\end{bmatrix}
\end{array}
\]
Putting it together and written in explicit form:

\[
\begin{pmatrix}
  x(L) \\
  x'(L)
\end{pmatrix}
= \begin{pmatrix}
  x_0 + \frac{L}{2} \cdot (x'_0 + x'(L)) \\
  x'_0 + L \cdot f(x_0 + \frac{L}{2} x'_0)
\end{pmatrix}
\]

\[
x(L) \approx x_0 + L \cdot x'_0 + \frac{L^2}{2} \cdot f(x_0 + \frac{L}{2} x'_0)
\]

(using: \( f(z + \Delta z) \approx f(z) + f'(z) \cdot \Delta z \) for small \( \Delta z \))

\[
x(L) \approx x_0 + L \cdot x'_0 + \frac{L^2}{2} \cdot f(x_0) + \frac{L^3}{4} \cdot f'(x_0)x'_0
\]

It is symplectic !!
Comparison:

the (exact, but non-symplectic) Taylor expansion of $f(x)$ gives:

$$x(L) = x_0 + x_0' L + \frac{L^2}{2} f(x_0) + \frac{L^3}{6} f'(x_0)x_0' + ...$$

the (approximate, but symplectic) algorithm gives:

$$x(L) = x_0 + x_0' L + \frac{L^2}{2} f(x_0) + \frac{L^3}{4} f'(x_0)x_0' + ...$$

Errors are $O(L^3)$ (is correct to $O(L^2)$ by construction)

Errors are $O(L^5)$ for the $O(L^4)$ (3 kicks) scheme

For small $L$ acceptable, and symplectic

just for illustration: $\frac{L^3_{\text{decapole}}}{L^3_{\text{dipole}}} \approx 10^{-7}$
An application, a (1D) sextupole with:

\[ f(x) = k \cdot x^2 \]

using the thin lens approximation gives:

\[ x(L) = x_0 + x'_0 L + \frac{1}{2} k x_0^2 L^2 + \frac{1}{2} k x_0 x'_0 L^3 + \ldots \]

\[ x'(L) = x'_0 + k x_0^2 L + k x_0 x'_0 L^2 + \frac{1}{4} k x_0^2 L^3 + \ldots \]

Map for thick sextupole of length \( L \) in thin lens approximation, accurate to \( O(L^2) \)
Short summary: thin lens computations

- Are exactly symplectic
- Simulations based on thin lenses fast and efficient
  successfully applied to large (storage) rings (e.g. SPS, Tevatron, LHC, LEP, ...)

But they do not represent an exact model of the accelerator

If used blindly: .. an exact solution to a wrong problem

For (large) accelerators the thin lenses are usually a good approximation
and tool (because we do not have to go to very high-order integrators to
get proper results).

An extension and more accurate treatment in particular for non-linear
elements in terms of Hamiltonian dynamics
