Linear Accelerators

David Alesini (INFN-LNF, Frascati, Rome, Italy)

Introduction to Accelerator Physics

2 - 14 October, 2016

Danubius Hotel Helia, Budapest, Hungary

ACKNOWLEDGEMENTS

Several pictures, schemes, images and plots have been taken from papers and previous presentations of the following authors that I would like to thank.

I would like to acknowledge in particular the following authors:

A. Gallo, E. Jensen, A. Lombardi, F. Tecker and M. Vretenar

I would like also to acknowledge the following authors:

Hans Weise, Sergey Belomestnykh, Dinh Nguyen, John Lewellen, Leanne Duffy, Gianluigi Ciovati, Jean Delayen, S. Di Mitri, R. Carter, G. Bisoffi, B. Aune, J. Sekutowicz, H. Safa, D. Proch, H. Padamsee, R. Parodi, Paolo Michelato, Terry Garvey, Yujong Kim, S. Saitiniyazi, M. Mayierjiang, M. Titberidze, T. Andrews, C. Eckman, Roger M. Jones, T. Inagaki, T. Shintake, F. Löhl, J. Alex, H. Blumer, M. Bopp, H. Braun, A. Citterio, U. Ellenberger, H. Fitze, H. Joehri, T. Kleeb, L. Paly, J.Y. Raguin, L. Schulz, R. Zennaro, C. Zumbach. Detlef Reschke, David Dowell, K. Smolenski, I. LINAC: BASIC DEFINITION AND MAIN COMPONENTS

LINAC (linear accelerator) is a **system that allows to accelerate charged particles through a linear trajectory** by electromagnetic fields.

LINAC TECHNOLOGY COMPLEXITY

LINAC: BASIC DEFINITION AND MAIN COMPONENTS

LINAC (linear accelerator) is a **system that allows to accelerate charged particles through a linear trajectory** by electromagnetic fields.

LORENTZ FORCE: ACCELERATION AND FOCUSING

The basic equation that describes the acceleration/bending/focusing processes is the **Lorentz Force**. Particles are accelerated through electric fields and are bended and focused through magnetic fields.

 $\vec{p} = momentum$

m = mass

Transverse Dynamics

$$\vec{v} = velocity$$

 $\frac{d\vec{p}}{dt} = q\left(\vec{E} + \vec{v} \times \vec{B}\right)$ q = charge**BENDING AND FOCUSING ACCELERATION** 2^{nd} term always perpendicular to motion => no To accelerate, we need a force in the energy gain direction of motion v beam +q

ACCELERATION: SIMPLE CASE

The first historical linear particle accelerator was built by the Nobel prize Wilhelm Conrad Röntgen (1900). It consisted in a vacuum tube containing a cathode connected to the negative pole of a DC voltage generator. **Electrons emitted by the heated cathode** were accelerated while flowing to another electrode connected to the positive generator pole (anode). Collisions between the energetic electrons and the anode produced **X-rays**.

The **energy gained** by the electrons travelling from the cathode to the anode is equal to their charge multiplied the DC voltage between the two electrodes.

$$\frac{d\vec{p}}{dt} = q\vec{E} \implies \Delta E = q\Delta V$$

$$\vec{p}$$
 = momentum
 q = charge
 E = energy

Particle energies are typically expressed in electron-volt [eV], equal to the energy gained by 1 electron accelerated through an electrostatic potential of 1 volt: 1 eV=1.6x10⁻¹⁹ J

ELECTROSTATIC ACCELERATORS

To increase the achievable maximum energy, Van de Graaff invented an electrostatic generator based on a dielectric belt transporting positive charges to an isolated electrode hosting an ion source. The positive ions generated in a large positive potential were accelerated toward ground by the static electric field.

DC voltage as large as ~10 MV can be obtained (E~10 MeV). The main limit in the achievable insulation

APPLICATIONS OF DC ACCELERATORS

voltage is the **breakdown** due to

LIMITS OF ELECTROSTATIC ACCELERATORS

DC particle accelerators are in operation worldwide, typically at V<15MV (E_{max}=15 MeV), I<100mA. They are used for:

 \Rightarrow material analysis

problems.

- \Rightarrow X-ray production,
- \Rightarrow ion implantation for semiconductors
- \Rightarrow first stage of acceleration (particle sources)

750 kV Cockcroft-Walton Linac2 injector at CERN from 1978 to 1992

RF ACCELERATORS : WIDERÖE "DRIFT TUBE LINAC" (DTL)

Basic idea: the particles are accelerated by the electric field in the gap between electrodes connected alternatively to the poles of an AC generator. This original idea of Ising (1924) was e⁻⁻ implemented by Wideroe (1927) who applied a sine-wave voltage to a sequence of drift tubes. The particles do not experience any force while travelling inside the tubes (equipotential regions) and are accelerated across the gaps. This kind of structure is called Drift Tube LINAC (DTL).

 \Rightarrow If the **length of the tubes** increases with the particle velocity during the acceleration such that the time of flight is kept constant and equal to half of the RF period, the particles are subject to a **synchronous accelerating voltage** and experience an energy gain of $\Delta E = q \Delta V$ at each gap crossing.

 \Rightarrow In principle a single **RF generator** can be used to indefinitely accelerate a beam, **avoiding the breakdown limitation** affecting the electrostatic accelerators.

⇒The Wideroe LINAC is the **first RF LINAC**

PARTICLE VELOCITY VS ENERGY: LIGHT AND HEAVY PARTICLES

Single

rest energy E_0 (= m_0c^2) total energy E mass *m* particle velocity v momentum *p* (=*mv*) Kinetic energy $W=E-E_0$

rest mass m_o

Relativistic factor $\beta = v/c$ (<1) **Relativistic factor** $\gamma = E/E_0 (\geq 1)$ $\mathbf{f}^2 = E_0^2 + p^2 c^2$

 $\beta = \sqrt{1 - \frac{1}{\gamma^2}} = \sqrt{1 - \left(\frac{E_0}{E}\right)^2} = \sqrt{1 - \left(\frac{E_0}{E_0 + W}\right)^2}$

$$\beta = \sqrt{1 - 1/\gamma^2}$$

$$\gamma = 1/\sqrt{1 - \beta^2}$$

$$W = (\gamma - 1)m_0 c^2 \approx \frac{1}{2}m_0 v^2 \text{ if } \beta <<1$$

 \Rightarrow Light particles (as electrons) are practically fully relativistic ($\beta \cong 1$, $\gamma > 1$) at relatively low energy and reach a constant velocity (~c). The acceleration process occurs at constant particle velocity

⇒Heavy particles (protons and ions) are typically weakly relativistic and reach a constant velocity only at very high energy. The velocity changes a lot during acceleration process.

 \Rightarrow This implies important differences in the technical characteristics of the accelerating structures. In particular for protons and ions we need different types of accelerating structures, optimized for different velocities and/or the accelerating structure has to vary its geometry to take into account the velocity variation.

ACCELERATION: ENERGY GAIN

We consider the acceleration between two electrodes in DC.

RF ACCELERATION: BUNCHED BEAM

We consider now the acceleration between two electrodes fed by an RF generator

DRIFT TUBE LENGTH AND FIELD SYNCHRONIZATION

If now we consider a DTL structure with an injected particle at an energy E_{in} , we have that at each gap the energy gain is $\Delta E_n = qV_{RF}$ and the particle increase its velocity accordingly to the previous relativistic formulae.

ACCELERATION WITH HIGH RF FREQUENCIES: RF CAVITIES

There are two important **consequences** of the previous obtained formulae:

The condition $L_n << \lambda_{RF}$ (necessary to model the tube as an equipotential region) requires $\beta << 1$. \Rightarrow The Wideröe technique can not be applied to relativistic particles.

$$\frac{\Delta E}{\Delta L} = \frac{qV_{RF}}{L_n} = qE_{RF} = \frac{2qV_{RF}}{\lambda_{RF}\beta_n}$$

Moreover when particles get high velocities the drift spaces get longer and one looses on the efficiency. The **average accelerating** gradient (E_{RF} [V/m]) increase pushes towards small λ_{RF} (high frequencies).

High frequency high power sources became available after the 2^{nd} world war pushed by military technology needs (such as radar). However, the concept of equipotential DT can not be applied at small λ_{RF} and the power lost by radiation is proportional to the RF frequency.

As a consequence we must consider accelerating structures different from drift tubes. \Rightarrow The solution consists of **enclosing the system in a cavity** which resonant frequency matches the RF generator frequency.

 \Rightarrow Each cavity can be independently powered from the RF generator

waveguide

RF CAVITIES

 \Rightarrow High frequency RF accelerating fields are confined in , cavities.

 \Rightarrow The cavities are **metallic closed volumes** were the e.m fields has a particular spatial configuration (**resonant modes**) whose components, including the accelerating field \mathbf{E}_{z} , oscillate at some specific frequencies \mathbf{f}_{RF} (resonant frequency) characteristic of the mode.

 \Rightarrow The modes are excited by **RF generators** that are **coupled to the cavities** through waveguides, coaxial cables, etc...

⇒The resonant modes are called **Standing Wave (SW) modes** (spatial fixed configuration, oscillating in time).

 \Rightarrow The spatial and temporal field profiles in a cavity have to be computed (analytically or numerically) **by solving the Maxwell equations** with the proper boundary conditions.

Ε

ALVAREZ STRUCTURES

Alvarez's structure can be described as a special DTL drift tubes radio-frequency cavity power source in which the electrodes are part of a resonant macrostructure. RF Generator beam Accelerated Particle Particles Source © Encyclopaedia Britannica, inc \Rightarrow The DTL operates in **0 mode** for protons and ions in the range β =0.05-0.5 (f_{RF}=50-400 MHz) 1-100 MeV; \Rightarrow The beam is inside the "drift tubes" when the Ez electric field is decelerating. The electric field is concentrated between gaps; Ζ \Rightarrow The drift tubes are suspended by **stems**; ⇒Quadrupole (for transverse focusing) can fit inside the drift tubes. \Rightarrow In order to be synchronous with the accelerating field at each gap the length of the **n-th drift tube** L_n has to be: $L_n = \beta_n \lambda_{RF}$ Quadrupole Drift tube

ALVAREZ STRUCTURES: EXAMPLES

CERN LINAC 2 tank 1: 200 MHz 7 m x 3 tanks, 1 m diameter, final energy 50 MeV.

CERN LINAC 4: 352 MHz frequency, Tank diameter 500 mm, 3 resonators (tanks), Length 19 m, 120 Drift Tubes, Energy: 3 MeV to 50 MeV, β =0.08 to 0.31 \rightarrow cell length from 68mm to 264mm.

HIGH β CAVITIES: CYLINDRICAL STRUCTURES

 \Rightarrow When the β of the particles increases (>0.5) one has to use **higher RF frequencies** (>400-500 MHz) to increase the accelerating gradient per unit length

⇒the **DTL structures became less efficient** (effective accelerating voltage per unit length for a given RF power);

Real cylindrical cavity

 $(TM_{010}$ -like mode because of the shape and

Cylindrical single or multiple cavities working on the **TM**₀₁₀-like mode are used

For a **pure cylindrical structure** (also called **pillbox cavity**) the first accelerating mode (i.e. with non zero longitudinal electric field on axis) is the TM_{010} mode. It has a well known analytical solution from Maxwell equation.

The shunt impedance is the parameter that qualifies the **efficiency of an accelerating mode**. The higher is its value, the larger is the obtainable accelerating voltage for a given power. Traditionally, it is the quantity to optimize in order to **maximize the accelerating field for a given dissipated power**:

$$R = \frac{V_{acc}^2}{2P_{diss}} \left[\Omega\right]$$

NC cavity $Q \sim 10^4$ SC cavity $Q \sim 10^{10}$

SC cavity R~1T Ω

Example: R~0.5MΩ P_{diss}=1 MW V_{acc}=1MV

For a cavity working at 1 GHz with a structure length of 10 cm we have an average accelerating field of 10 MV/m

- In a multi-cell structure there is one RF input coupler. As a consequence the total number of RF sources is reduced, with a simplification of the layout and reduction of the costs;
- The **shunt impedance is n time** the impedance of a single cavity
- They are **more complicated** to fabricate than single cell cavities;
- The fields of adjacent cells couple through the cell **irises** and/or through properly designed coupling **slots**.

MULTI-CELL SW CAVITIES: π MODE STRUCTURES

- The N-cell structure behaves like a system composed by N coupled oscillators with N coupled multi-cell resonant modes.
- The modes are characterized by a cell-to-cell phase advance given by:

 $\Delta \phi_n = \frac{n\pi}{N-1} \qquad n = 0, 1, \dots, N-1$

- The multi cell mode generally used for acceleration is the π , $\pi/2$ and 0 mode (DTL as example operate in the 0 mode).
- In this case as done for the DTL structures the cell length has to be chosen in order to synchronize the accelerating field with the particle traveling into the structure at a certain velocity

 \Rightarrow For **ions and protons** the cell length has to be increased and the linac will be made of a sequence of different accelerating structures matched to the ion/proton velocity.

 \Rightarrow For **electron**, β =1, d= $\lambda_{RF}/2$ and the linac will be made of an injector followed by a series of identical accelerating structures, with cells all the same length.

π MODE STRUCTURES: EXAMPLES

LINAC 4 (CERN) PIMS (PI Mode Structure) for protons: f_{RF} =352 MHz, β >0.4

European XFEL (Desy): electrons

800 accelerating cavities 1.3 GHz / 23.6 MV/m

MULTI-CELL SW CAVITIES: $\pi/2$ MODE STRUCTURES

 \Rightarrow It is possible to demonstrate that **over a certain number of cavities** (>10) working on the π mode, the **overlap between adjacent modes** can be a problem (as example the field uniformity due to machining errors is difficult to tune).

⇒The criticality of a working mode depend on the **frequency** separation between the working mode and the adjacent mode

 \Rightarrow the $\pi/2$ mode from this point of view is the most stable mode. For this mode it is possible to demonstrate that the accelerating field is zero every two cells. For this reason the empty cells are put of axis and coupling slots are opened from the accelerating cells to the empty cells.

 \Rightarrow this allow to increase the number of cells to >20-30 without problems

Side Coupled Cavity (SCC)

 $f_{\text{RF}}\text{=}800$ - 3000 MHz for proton ($\beta\text{=}0.5\text{-}1\text{)}$ and electrons

SCC STRUCTURES: EXAMPLES

Spallation Neutron Source Coupled Cavity Linac (protons)

4 modules, each containing 12 accelerator segments CCL and 11 bridge couplers. The CCL section is a RF Linac, operating at **805 MHz** that accelerates the beam **from 87 to 186 MeV** and has a physical installed length of slightly over **55 meters.**

TRAVELLING WAVE (TW) STRUCTURES

 \Rightarrow To accelerate charged particles, the electromagnetic field must have an **electric field along the direction of propagation of the particle**.

 \Rightarrow The field has to be synchronous with the particle velocity.

 \Rightarrow Up to now we have analyzed the cases standing **standing wave (SW)** structures in which the field has basically a given profile and oscillate in time (as example in DTL or **resonant cavities operating on the** TM₀₁₀-like).

 \Rightarrow There is another possibility to accelerate particles: using a **travelling wave (TW)** structure in which the RF wave is **co-propagating** with the beam with a **phase velocity equal to the beam velocity**.

 \Rightarrow Typically these structures **are used for electrons** because in this case the **phase velocity can be constant** all over the structure and equal to c. On the other hand it is difficult to modulate the phase velocity itself very quickly for a low β particle that changes its velocity during acceleration.

TW CAVITIES: CIRCULAR WAVEGUIDE AND DISPERSION CURVE

In **TW structures** an e.m. wave with $E_z \neq 0$ travel together with the beam in a special guide in which the **phase velocity of the wave matches the particle velocity (v)**. In this case the beam absorbs energy from the wave and it is **continuously accelerated**.

As example if we consider a simple circular waveguide the first propagating mode with $E_z \neq 0$ is the TM₀₁ mode. Nevertheless by solving the wave equation it turns out that an e.m. wave propagating in this **constant cross section waveguide** will **never be synchronous with a particle beam** since the **phase velocity is always larger than the speed of light c**.

TW CAVITIES: IRIS LOADED STRUCTURES

In order to slow-down the wave phase velocity, iris-loaded periodic structure have to be used.

TW CAVITIES: CONSTANT GRADIENT STRUCTURES

In a TW structure, the **RF power enters** into the cavity through an input coupler, flows (travels) through the cavity in the same direction as the beam and an output coupler at the end of the structure is connected to a matched power load.

If there is no beam, the input power reduced by the cavity losses goes to the power load where it is dissipated.

In the presence of a large beam current, however, a fraction of the TW power is transferred to the beam.

purely periodic structure, In a made by a sequence of identical called "constant cells (also impedance structure"), the RF power flux and the intensity of the accelerating field decav exponentially along the structure :

$$E_z(z) = E_0 e^{-\alpha z}$$

It is possible to demonstrate that, in order to keep the accelerating field constant along the structure, the iris apertures have to decrease along the structure.

$$E_z(z) =$$

LINAC TECHNOLOGY

ACCELERATING CAVITY TECHNOLOGY

 \Rightarrow The structures are powered by RF generators (like **klystrons**).

 \Rightarrow The cavities (and the related LINAC technology) can be of different material:

- **copper** for **normal conducting (NC, both SW than TW)** cavities; -
- Niobium for superconducting cavities (SC, SW);

 \Rightarrow We can choose between NC or the SC technology depending on the required performances in term of:

- accelerating gradient (MV/m);
- **RF pulse length** (how many bunches we can contemporary accelerate);
- Duty cycle: pulsed operation (i.e. 10-100 Hz) or continuous wave (CW) operation;
- Average beam current.

NIOBIUM

NORMAL CONDUCTING AND SUPER CONDUCTING

NC: COPPER

The most widely used NC metal for RF structures is **OFHC copper** (Oxigen free high conductivity) for several reasons:

- 1) Easy to machine (good achievable roughness at the few nm level)
- 2) Easy to braze/weld
- 3) Easy to find at relatively low cost
- 4) Very good electrical (and thermal) conductivity
- 5) Low SEY (multipacting phenomena)
- 6) Good performances at high accelerating gradient

- -Higher dissipation
- -Pulsed operation
- -Higher peak accelerating gradient (up to 50-100 MV/m)
- -Standard cleaning procedures for the cavity fabrication
- -Cooling of dissipated power with pipes

SC: NIOBIUM

The most common material for SC cavities is Nb because:

- 1) Nb has a relatively **high transition temperature** (Tc=9.25 K).
- 2) SC can be destroyed by magnetic field greater than a critical field $H_c \Rightarrow$ Pure Nb has a **relatively high** critical magnetic field Hc=170-180 mT.
- 3) It is chemically inert

-lower dissipation

-Allow continuous operation

gradient (max 30-40 MV/m)

-Special cleaning procedures for

-They need a cryostat to reach

the SC temperature of few K

-lower peak accelerating

the cavity fabrication

- 4) It can be machined and deep-drawn
- 5) It is available as bulk and sheet material in any size, fabricated by forging and rolling....

RF STRUCTURE AND BEAM STRUCTURE

The "**beam structure**" in a LINAC is directly related to the "**RF structure**". There are basically two possible type of operations:

- CW (continuous wave) \Rightarrow allow, in principle, to operate with a continuous beam
- PULSED OPARATION ⇒ there are RF pulses at a certain repetition rate (Duty Cycle (DC)=pulsed width/period)

 \Rightarrow Because of the very low power dissipation and low RF power required to achieve a certain accelerating voltage the SC structures allow operation at very high Duty Cycle (DC) up to a CW operation with high gradient (>20 MV/m).

⇒On the other hand **NC structures can operate in pulsed mode** at very low DC with **higher peak field** (TW structures can >50-80 MV/m peak field).

 \Rightarrow NC structures can also operate in CW but at very low gradient because of the dissipated power.

EXAMPLE FABRICATION PROCESS:NC TW STRUCTURES

The cells and couplers are fabricated with milling machines and lathes starting from **OFHC forged or laminated copper** with precisions that can be of the order of few um and surface roughness <50 nm.

The cells are then piled up and **brazed** together in vacuum or hydrogen furnace using different alloys at different temperatures (700-1000 C) and/or in different steps.

Nb is available as **bulk and sheet material** in any size, fabricated by forging and rolling. High Purity Nb is made by electron beam melting under good vacuum.

The most common fabrication techniques for the cavities are to deep draw or spin half-cells.

Alternative techniques are: hydroforming, spinning an entire cavity out of single sheet or tube and Nb sputtering

After forming the parts are electron beam welded together

μm

• RF tuning

The cavity treatment after the welding is quite complicated

• buffered chemical polishing (BCP), electropolishing and

• rinsed with ultraclean water also at high pressure (100 bar)

• Thermal treatments up to >1000 C to diffuse H_2 out of the

• **high-temperature treatment** with Ti getter (post-purification)

etching to remove surface damaged layers of the order of 100

CAVITY TREATMENT

and require several steps between:

material increasing the Nb purity (RRR)

Forming	I WHY
EB Welding	Clean welding
Ti purification	RRR enhancement
hemical etching 100-200 µm EP	Remove contamination and damage layer
Annealing 800°C, 2h (or 600°C, 10h)	Get rid of hydrogen
hemical etching 5-20 μm	Remove diffusion layer (O, C, N)
Spe <mark>cific rin</mark> sing	e.g. remove S particles due to EP
High pressure rinsing (HPR)	Get rid of dust particles
Assembling	Ancillaries : antennas, couplers , vacuum ports
king, 120°C, 48h	Decrease high field losses (Q-drop)
Post processing	Get rid of "re-contamination" ?
Test RF	Cavity's performance
processing, HPP	Decrease field emission

EXAMPLES: EUROPEAN XFEL

EXAMPLE: SWISSFEL LINAC (PSI)

LINAC: BASIC DEFINITION AND MAIN COMPONENTS

LINAC (linear accelerator) is a **system that allows to accelerate charged particles through a linear trajectory** by electromagnetic fields.

ELECTRON SOURCES: RF PHOTO-GUNS

RF guns are used in the first stage of electron beam generation in FEL and acceleration.

- Multi cell: typically 2-3 cells
- SW π mode cavities
- operate in the range of 60-120 MV/m cathode peak accelerating field with up to 10 MW input power.
- Typically in L-band- S-band (1-3 GHz) at 10-100 Hz.
- Single or multi bunch (L-band)
- Different type of cathodes (copper,...)

The electrons are emitted on the **cathode** through a laser that hit the surface. They are then accelerated trough the electric field that has a longitudinal component on axis TM_{010} .

z [mm]

RF PHOTO-GUNS: EXAMPLES

LCLS

Frequency = 2,856 MHz Gradient = 120 MV/m Exit energy = 6 MeV Copper photocathode RF pulse length \sim 2 µs Bunch repetition rate = 120 Hz Norm. rms emittance 0.4 mm·mrad at 250 pC

PITZ L-band Gun

Frequency = 1,300 MHz Gradient = up to 60 MV/m Exit energy = 6.5 MeV Rep. rate 10 Hz Cs_2 Te photocathode RF pulse length ~1 ms 800 bunches per macropulse Normalized rms emittance 1 nC 0.70 mm·mrad 0.1 nC 0.21 mm·mrad

Solenoids field are used to compensate the space charge effects in low energy guns. The configuration is shown in the picture

ION SOURCES

Basic principle: create a plasma and optimize its conditions (heating, confinement and loss mechanisms) to produce the desired ion type. Remove ions from the plasma via an aperture and a strong electric field.

SUMMARIZING THE FIRST PART

LINAC: BASIC DEFINITION AND MAIN COMPONENTS

LINAC (linear accelerator) is a **system that allows to accelerate charged particles through a linear trajectory** by electromagnetic fields.

SYNCHRONOUS PARTICLE/PHASE

 \Rightarrow Let us consider a SW linac structure made by accelerating gaps (like in DTL) or cavities.

 \Rightarrow In each gap we have an accelerating field oscillating in time and an integrated accelerating voltage (V_{acc}) still oscillating in time than can be expressed as:

$$V_{acc} = V_{RF} \cos(\omega_{RF} t + \theta)$$

⇒Let's assume that the "perfect" synchronism condition is fulfilled for a phase ϕ_s (called *synchronous phase*). This means that a particle (called *synchronous particle*) entering in a gap with a phase ϕ_s ($\phi_s = \omega_{RF} t_s$) with respect to the RF voltage receive a **energy gain** (and a consequent change in velocity) that allow entering in the subsequent gap with the **same phase** ϕ_s and so on.

 \Rightarrow for this particle the energy gain in each gap is:

$$\Delta E = q \underbrace{V_{RF} \cos(\phi_s + \theta)}_{V_{acc_s}} = q V_{acc_s}$$

 \Rightarrow obviously both ϕ_s and ${\phi_s}^*$ are synchronous phases.

PRINCIPLE OF PHASE STABILITY

⇒Let us consider now the first synchronous phase ϕ_s (on the positive slope of the RF voltage). If we consider **another particle** "near" to the synchronous one **that arrives later in the gap** $(t_1>t_s, \phi_1>\phi_s)$, it will see an higher voltage, it will gain an higher energy and an higher velocity with respect to the synchronous one. As a consequence its time of flight to next gap will be shorter, partially **compensating its initial delay**.

⇒Similarly if we consider another particle "near" to the synchronous one that arrives before in the gap $(t_1 < t_s, \phi_1 < \phi_s)$, it will see a smaller voltage, it will gain a smaller energy and a smaller velocity with respect to the synchronous one. As a consequence its time of flight to next gap will be longer, compensating the initial advantage.

 \Rightarrow **On the contrary** if we consider now the synchronous particle at phase ϕ_s^* and another particle "near" to the synchronous one that arrives later or before in the gap, it will receive an energy gain that will increase further its distance form the synchronous one

 \Rightarrow The choice of the synchronous phase in the positive slope of the RF voltage provides longitudinal focusing of the beam: **phase stability principle**.

 \Rightarrow The synchronous phase on the negative slope of the RF voltage is, on the contrary, **unstable**

 \Rightarrow Relying on particle velocity variations, **longitudinal focusing does not work for fully relativistic beams** (electrons). In this case acceleration "on crest" is more convenient.

ENERGY-PHASE EQUATIONS (1/2)

In order to study the **longitudinal dynamics in a LINAC**, the following variables are used, which describe the generic particle **phase** (time of arrival) and **energy with respect to the synchronous particle**:

The energy gain per cell (one gap + tube in case of a DTL) of a generic particle and of a synchronous particle are (we put θ =0 in the generic expression of the accelerating voltage just for simplicity):

ENERGY-PHASE EQUATIONS (2/2)

On the other hand we have that the **phase variation per cell** of a generic particle and of a synchronous particle are:

$$\omega_{RF}\left(\frac{1}{v}-\frac{1}{v_s}\right) = \omega_{RF}\left(\frac{v_s-v}{vv_s}\right) \underset{\substack{vv_s \cong v_s^2 \\ v-v_s \cong \Delta v}}{\cong} - \frac{\omega_{RF}}{c} \frac{\Delta\beta}{\beta_s^2} \text{ remembering that } \beta = \sqrt{1-1/\gamma^2} \Rightarrow \beta d\beta = d\gamma/\gamma^3 \Rightarrow -\frac{\omega_{RF}}{c} \frac{\Delta\beta}{\beta_s^2} \cong -\frac{\omega_{RF}}{c} \frac{\Delta\gamma}{\beta_s^3\gamma_s^3} = -\frac{\omega_{RF}}{c} \frac{\Delta\beta}{\beta_s^2\gamma_s^3}$$

SMALL AMPLITUDE ENERGY-PHASE OSCILLATIONS

Assuming small oscillations around the synchronous particle that allow to approximate $\cos(\phi_s + \varphi) - \cos\phi_s \cong \varphi \sin\phi_s$ $\frac{dw}{dz} = qE_{RF}\left[\cos(\phi_s + \varphi) - \cos\phi_s\right]$ Deriving both terms with respect to z and Deriving both terms with respect to z and assuming an **adiabatic acceleration** process i.e. a particle energy and speed $\frac{d\left(\frac{\omega_{RF}}{cE_0\beta_s^3\gamma_s^3}\right)}{dz}w \ll \frac{\omega_{RF}}{cE_0\beta_s^3\gamma_s^3}\frac{dw}{dz}$ variations that allow to consider $\frac{d^2\varphi}{dz^2} = -\frac{\omega_{RF}}{cE_{\circ}\beta^3\gamma^3}$ $\frac{d\varphi}{dz} = -\frac{\omega_{RF}}{cE_0\beta_s^3\gamma_s^3} w$ $\frac{d^2\varphi}{dz^2} + q \frac{\omega_{RF} E_{RF} \sin(-\phi_s)}{cE_0 \beta_s^3 \gamma_s^3} \varphi = 0$ harmonic oscillator equation \Rightarrow The condition to have stable longitudinal oscillations and acceleration at the same time is: $\left.\begin{array}{l}
\Omega_s^2 > 0 \Rightarrow \sin(-\phi_s) > 0 \\
V_{acc} > 0 \Rightarrow \cos\phi_s > 0
\end{array}\right\} \Rightarrow -\frac{\pi}{2} < \phi_s < 0$ if we accelerate on the rising part of the positive RF wave we have a longitudinal force keeping the beam bunched _V_{acc} around the synchronous phase.

V_{acc}

V_{max}

 $\Phi_{\rm s}$

$$\begin{cases} \varphi = \hat{\varphi} \cos\left(\Omega_{s} z\right) \\ w = \hat{w} \sin\left(\Omega_{s} z\right) \end{cases}$$

ENERGY-PHASE OSCILLATIONS IN PHASE SPACE

0

The energy-phase oscillations can be drawn in the longitudinal phase space:

$$\begin{cases} \varphi = \hat{\varphi} \cos\left(\Omega_{s} z\right) \\ w = \hat{w} \sin\left(\Omega_{s} z\right) \end{cases}$$

 \Rightarrow The trajectory of a generic particle in the longitudinal phase space is an **ellipse**.

 \Rightarrow The maximum energy deviation is reached at $\phi=0$ while the maximum phase excursion corresponds to w=0.

 \Rightarrow the bunch occupies an area in the longitudinal phase space called **longitudinal emittance** and the projections of the bunch in the energy and phase planes give the **energy spread** and the **bunch length**.

 \Rightarrow It is easy to shown that

$$\frac{\hat{w}}{\hat{\varphi}} = \left(-\frac{cqE_{RF}E_0\sin(-\phi_s)\beta_s^3\gamma_s^3}{\omega_{RF}}\right)^{1/2}$$

The parameter of the ellipse vary (slowly) during acceleration

 $\Rightarrow \text{numerical} \quad \text{example:} \\ \text{Protons @ 100 MeV, } E_{\text{RF}} = 5 \\ \text{MV/m;} \quad \varphi_{\text{s}} = -30^{\circ}; \text{ } f_{\text{RF}} = 300 \quad \clubsuit \quad \Omega_{s} \approx 0.4 \text{ } rad \text{ } \text{/ } m \quad ; \text{ } \lambda_{s} = \frac{2\pi}{\Omega_{s}} = 15.7 \text{ } m \\ \text{MHz} \\ \end{array}$

ADIABATIC PHASE DAMPING

⇒According to Liouville's theorem, under the action of conservative forces, the ellipse area in phase space is constant.

 \Rightarrow The amplitude of the synchrotron oscillations remains **rigorously constant** only at **constant energy** (which is not the case in accelerators!), while in case of slow acceleration (low gradients) the **oscillation amplitudes** will **smoothly change** to satisfy the **Liouville's theorem**. In fact: W

LARGE OSCILLATIONS

To study the longitudinal dynamics **at large oscillations**, we have to consider the **non linear system of differential equations** without approximations. By neglecting particle energy and speed variations along the LINAC (**adiabatic acceleration**) it is possible to obtain easily the following relation between w and φ that is the **Hamiltonian of the system** related to the total particle energy.

$$\frac{1}{2} \left(\frac{\omega_{RF}}{cE_0 \beta_s^3 \gamma_s^3} \right)^2 w^2 + \frac{\omega_{RF} qE_{RF}}{cE_0 \beta_s^3 \gamma_s^3} \left[\sin(\phi_s + \varphi) - \varphi \cos \phi_s - \sin(\phi_s) \right] = \text{const} = \text{H}$$

 \Rightarrow For each H we have different trajectories in the longitudinal phase space

⇒the oscillations are **stable** within a region bounded by a special curve called **separatrix**: its equation is:

$$\frac{1}{2}\frac{\omega_{RF}}{cE_0\beta_s^3\gamma_s^3}w^2 + qE_{RF}[\sin(\phi_s+\varphi)-(2\varphi_s+\varphi)\cos\phi_s+\sin(\phi_s)] = 0$$

 \Rightarrow the region inside the separatrix is called **RF bucket**. The dimensions of the bucket shrinks to zero if ϕ_s =0.

 \Rightarrow trajectories outside the RF buckets are **unstable**.

 \Rightarrow we can define the **RF** acceptance as the maximum extension in phase and energy that we can accept in an accelerator:

$$\Delta \varphi \Big|_{MAX} \cong 3\phi_s$$

$$\Delta w \Big|_{MAX} = \pm 2 \left[\frac{qcE_o \beta_s^3 \gamma_s^3 E_{RF} (\phi_s \cos \phi_s - \sin \phi_s)}{\omega_{RF}} \right]^{\frac{1}{2}}$$

LONGITUDINAL DYNAMICS OF LOW ENERGY ELECTRONS (1/3)

From previous formulae it is clear that there is **no motion in the longitudinal phase plane for ultrarelativistic particles** ($\gamma >>1$).

It is interesting to analyze what happen if we **inject** an electron beam produced by a cathode (at low energy) directly in a TW structure (with $v_{ph}=c$) and the conditions that allow to **capture** the beam (this is equivalent to consider instead of a TW structure a SW designed to accelerate ultrarelativistic particles at v=c).

Particles enter the structure with velocity v<c and, initially, they are not synchronous with the accelerating field and there is a so called slippage.

 \Rightarrow This is the case of **electrons** whose **velocity is always close to speed of light c** even at low energies.

 \Rightarrow Accelerating structures are designed to provide an accelerating field synchronous with particles moving at v=c. like **TW structures** with phase velocity equal to c.

LONGITUDINAL DYNAMICS OF LOW ENERGY ELECTRONS (2/3)

LONGITUDINAL DYNAMICS OF LOW ENERGY ELECTRONS (3/3)

\Rightarrow 2nd Result

For a given injection energy (β_{in}) and phase (ϕ_{in}) we can find which is the electric field (E_{RF}) that is necessary to have the completely relativistic beam at phase ϕ_{∞} (that is necessary to **capture the beam at phase \phi_{\infty}**)

Example:

$$E_{in} = 50 \text{ keV}$$
, (kinetic energy), $\phi_{in} = -\pi/2$, $\phi_{\infty} = 0 \Longrightarrow \gamma_{in} \approx 1.1$; $\beta_{in} \approx 0.41$
 $f_{RF} = 2856 \text{ MHz} \Longrightarrow \lambda_{RF} \approx 10.5 \text{ cm}$

We obtain $E_{RF} \cong 20 \text{MV/m}$;

 \Rightarrow 3rd Result

For a given injection energy we can find which is the **minimum value of the electric field** (E_{RF}) that allow to capture a beam. Obviously this correspond to an injection phase $\phi_{in} = -\pi/2$ and $\phi_{\infty} = \pi/2$.

Example: For the previous case we obtain: $E_{RF min} \cong 10 MV/m$;

 \Rightarrow 4th Result

It is possible to demonstrate that if we inject the beam at $\phi_{in} = -\pi/2$ (and $E_{RF} > E_{RF_MIN}$) we have that the captured beam is compressed (shortened) by the RF.

 $E_{RF_MIN} = \frac{\pi E_0}{\lambda a} \sqrt{\frac{1}{2}}$

BUNCHER AND CAPTURE SECTIONS

Once the capture condition $E_{RF}>E_{RF_{MIN}}$ is fulfilled the fundamental equation of previous slide sets the ranges of the injection phases ϕ_{in} actually accepted. Particles whose injection phases are within this range can be captured the other are lost.

In order to increase the capture efficiency of a traveling wave section, pre-bunchers are often used. They are SW cavities aimed at pre-forming particle bunches gathering particles continuously emitted by a source.

 \Rightarrow Bunching is obtained by modulating the energy (and therefore the velocity) of a continuous beam using the longitudinal E-field of a SW cavity. After a certain drift space the velocity modulation is converted in a density charge modulation. The density modulation depletes the regions corresponding to injection phase values incompatible with the capture process

 \Rightarrow A TW accelerating structure (**capture section**) is placed at an **optimal distance from the pre-buncher**, to capture a large fraction of the charge and accelerate it till relativistic energies. The **amount of charge lost is drastically reduced**, while the capture section provide also further beam bunching.

LINAC: BASIC DEFINITION AND MAIN COMPONENTS

LINAC (linear accelerator) is a **system that allows to accelerate charged particles through a linear trajectory** by electromagnetic fields.

LORENTZ FORCE: ACCELERATION AND FOCUSING

 $\frac{d\vec{p}}{dt} = q\left(\vec{E} + \vec{v} \times \vec{B}\right)$

Particles are accelerated through electric field and are bended and focalized through magnetic field. \vec{p} The basic equation that describe the acceleration/bending /focusing processes is the **Lorentz Force**.

 $\vec{p} = momentum$

m = mass

$$v = velocity$$

q = charge

ACCELERATION

To accelerate, we need a force in the direction of motion

BENDING AND FOCUSING

2nd term always perpendicular to motion => no energy gain

MAGNETIC QUADRUPOLE

Quadrupoles are used to **focalize the beam in the transverse plane**. It is a **4 poles magnet**:

 \Rightarrow B=0 in the center of the quadrupole

 \Rightarrow The **B** intensity increases linearly with the off-axis displacement.

 \Rightarrow If the quadrupole is focusing in one plane is defocusing in the other plane

SOLENOID

Also solenoids can be used for focalization of beams (in particular electron beams).

Particles that enter into a solenoidal field with a transverse component of the velocity (divergence) start to **spiralize describing circular trajectories**.

LINAC: BASIC DEFINITION AND MAIN COMPONENTS

LINAC (linear accelerator) is a **system that allows to accelerate charged particles through a linear trajectory** by electromagnetic fields.

RF DEFOCUSING

 \Rightarrow **Phase stability** principle requires that the accelerating voltage increase in time (dV_{acc}/dt>0)

 \Rightarrow According to Maxwell equations the **divergence of the field is zero** and this implies that in traversing one accelerating gap there is a focusing/defocusing term

 \Rightarrow especially for ions there is a **velocity variation** along the gap that has to be taken into account to correctly evaluate the effect of the transverse focusing/defocusing field

 \Rightarrow transverse defocusing ~1/ γ^2 disappears at relativistic velocity

 \Rightarrow for non relativistic particles this term represent a coupling between the longitudinal and the transverse beam dynamics

⇒Important consequence: in an electron linac, transverse and longitudinal dynamics are decoupled

MAGNETIC FOCUSING CONFIGURATION IN A LINAC

 \Rightarrow **Defocusing RF forces** or the natural divergence (emittance) of the beam need to be **compensated** and controlled by **focusing forces**.

 \Rightarrow As previously pointed out a quadrupole is focusing in one plane and defocusing on the other. It can be demonstrated that a global focalization is provides by **alternating quadrupoles** with opposite signs (doublets, triplets) like in an optical system.

 \Rightarrow A linac alternates accelerating sections with focusing sections.

 \Rightarrow By definition a **focusing period** is the length after which the structure is **repeated**.

 \Rightarrow The maximum allowed distance between focusing elements depends on beam energy and current and change in the different linac sections (from only one gap in the DTL to one or more multi-cell cavities at high energies).

TRANSVERSE OSCILLATIONS AND BEAM ENVELOPE

Due to the **alternating quadrupole focusing system** each particle perform **transverse oscillations along the LINAC**.

The **equation of motion in the transverse plane** (as example x) is of the type:

Term depending on the magnetic configuration

RF defocusing term

It is possible to demonstrate that the **single particle trajectory is a pseudo-sinusoid** described by the equation:

Characteristic function (Twiss β -function [m]) that depend on the magnetic and RF configuration

Depend on the initial conditions of the particle

The final transverse beam dimensions ($\sigma_{x,y}(s)$) varies along the linac and are contained within an **envelope**

SMOOTH APPROXIMATION, EXAMPLES

 \Rightarrow In case of "smooth approximation" of the LINAC (we consider a sort of average quadrupole focusing and RF defocusing effect) we obtain a simple harmonic motion along s of the type (β is constant):

SPACE CHARGE EFFECTS

In the longitudinal and transverse beam dynamics we have neglected up to now the effect of Coulomb repulsion between particles (space charge).

These effects cannot be neglected especially at **low energy and at high current** because the space charge forces scales as $1/\gamma^2$ and with the current I.

The individual particles satisfy the equation

$$\frac{d^2x}{ds^2} + K^2(s)x - F_{sc} = 0$$

External forces Space Charge forces (magnets+RF) that is in general nonlinear and beam current dependent In case of smooth approximation and ellipsoidal beam we

have:

$$K_{0} = \sqrt{\left(\frac{qGl}{2mc\gamma\beta}\right)^{2} - \frac{\pi qE_{RF}\sin(-\phi)}{mc^{2}\lambda_{RF}(\gamma\beta)^{3}} - \frac{3Z_{0}qI\lambda_{RF}(1-f)}{8\pi mc^{2}\beta^{2}\gamma^{3}r_{x}r_{y}r_{z}}}$$

I= beam current $r_{x,y,z}$ =ellipsoid semi-axis f= form factor Z₀=free space impedance (377 Ω) Space charge term

For ultrarelativistic **electrons** RF defocusing and space charge disappear and the external focusing is required to control the emittance and to stabilize the beam against instabilities.

COLLECTIVE EFFECT: WAKEFIELDS

Collective effects are all effects related to the number of particles. We already mentioned the space charge one that can give an increase of beam dimensions, defocusing, etc... The other effects are due to the **wakefield**. The passage of bunches through accelerating structures excites electromagnetic **field**. This field can have longitudinal and transverse components and, interacting with subsequent bunches (long range wakefield), **can affect the longitudinal and the transverse beam dynamics**. In particular the **transverse wakefields**, can drive an instability along the train called **multibunch beam break up** (BBU).

Several approaches are used to absorb these field :

- Loop couplers (several per cavity for different modes/orientations)
- Waveguide dampers
- Beam pipe absorbers (ferrite or ceramic)

RADIO FREQUENCY QUADRUPOLES (RFQ)

Electrodes

At low proton (or ion) energies (β ~0.01), space charge defocusing is high and quadrupole focusing is not very effective. Moreover cell length becomes small and conventional accelerating structures (DTL) are very inefficient. At this energies it is used a (relatively) new structure, the Radio Frequency Quadrupole (1970).

Courtesy M. Vretenar

These structures allow to simultaneously provide:

RFQ: PROPERTIES

1-Focusing

The resonating mode of the cavity (between the four electrodes) is a **focusing mode**: **Quadrupole mode** (TE_{210}). The alternating voltage on the electrodes produces an alternating focusing channel with the period of the RF (electric focusing does not depend on the velocity and is ideal at low β)

2-Acceleration

The vanes have a **longitudinal modulation** with period = $\beta\lambda_{RF}$ this creates a **longitudinal component of the electric field** that accelerate the beam (the modulation corresponds exactly to a series of RF gaps).

3-Bunching

The modulation period (distance between maxima) can be slightly adjusted to change the phase of the beam inside the RFQ cells, and the amplitude of the modulation can be changed to change the accelerating gradient. One can start at -90° phase (linac) with some **bunching cells**, progressively **bunch the beam** (adiabatic bunching channel), and only in the last cells switch on the **acceleration**.

The RFQ is the only linear accelerator that can accept a low energy continuous beam.

Opposite vanes (180°)

Adjacent vanes (90°)

RFQ: EXAMPLES

The 1st 4-vane RFQ, Los Alamos 1980: 100 KeV - 650 KeV, 30 mA, 425 MHz

The CERN Linac4 RFQ 45 keV – 3 MeV, 3 m 80 mA H-, max. 10% duty cycle

TRASCO @ INFN Legnaro Energy In: 80 keV Energy Out: 5 MeV Frequency 352.2 MHz Proton Current (CW) 30 mA

THE CHOICE OF THE FREQUENCY

linear dimensions f-1

- Dekensisten (

Structure dimensions	Scales with 1/f		
Shunt impedance (efficiency) per unit	NC structures r increases and this push to adopt higher frequencies $\propto f^{1/2}$		
length r	SC structures the power losses increases with f ² and, as a consequence, r scales with 1/f this push to adopt lower frequencies		
Power sources	At very high frequencies (>10 GHz) power sources are less available		
Mechanical realization	Cavity fabrication at very high frequency requires higher precision but, on the other hand, at low frequencies one needs more material and larger machines/brazing oven		
Bunch length	short bunches are easier with higher f (FEL)		
RF defocusing (ion linacs)	Increases with frequency (\propto f)		
Cell length ($\beta\lambda$ RF)	gth (βλRF) 1/f		
Wakefields more critical at high frequency ($w_{1/\infty}$ f ^{2,} w			

frequency f

Electron linacs tend to use higher frequencies (1-12 GHz) than ion linacs. SW SC: 500 MHz-1500 MHz TW NC: 3 GHz-12 GHz

Proton linacs use lower frequencies (100-800 MHz), increasing with energy (ex.: 350–700 MHz): compromise between focusing, cost and size.

Heavy ion linacs tend to use even lower frequencies (30-200 MHz), dominated by the low beta in the first sections

THE CHOICE OF THE ACCELERATING STRUCTURE

In general the choice of the accelerating structure depends on:

- \Rightarrow **Particle type**: mass, charge, energy
- \Rightarrow Beam current
- \Rightarrow **Duty cycle** (pulsed, CW)
- \Rightarrow Frequency
- \Rightarrow **Cost** of fabrication and of operation

Moreover a given accelerating structure has also a curve of efficiency (shunt impedance) with respect to the particle energies and the choice of one structure with respect to another one depends also on this.

As example a very general scheme is given in the Table (absolutely not exhaustive).

Cavity Type	β Range	Frequency	Particles
RFQ	0.01-0.1	40-500 MHz	Protons, Ions
DTL	0.05 – 0.5	100-400 MHz	Protons, Ions
SCL	0.5 – 1	600 MHz-3 GHz	Protons, Electrons
SC Elliptical	> 0.5-0.7	350 MHz-3 GHz	Protons, Electrons
тw	1	3-12 GHz	Electrons

APPENDIX: SEPARATRIX

To study the longitudinal dynamics at large oscillations, we have to consider the non linear system of differential equations without approximations. By neglecting particle energy and speed variations along the LINAC we obtain:

The restoring force *F* can not be considered purely elastic anymore and may by derived from a **potential function** according to the usual definition:

$$\frac{d^2\varphi}{dz^2} = -\frac{\omega_{RF}qE_{RF}}{cE_0\beta_s^3\gamma_s^3} \left[\cos(\phi_s + \varphi) - \cos\phi_s\right] = F$$

$$U = -\int_{0}^{\varphi} Fd\varphi' = \frac{\omega_{RF} qE_{RF}}{cE_{0}\beta_{s}^{3}\gamma_{s}^{3}} \left[\sin(\phi_{s} + \varphi) - \varphi\cos\phi_{s} - \sin(\phi_{s})\right]$$

With few simple passages we obtain an "energy conservation"-like law:

$$\frac{d}{dz} \left[\left(\frac{d\varphi}{dz} \right)^2 \right] = 2 \frac{d\varphi}{dz} \frac{d^2 \varphi}{dz^2} = 2 \frac{d\varphi}{dz} \cdot \left(-\frac{dU}{d\varphi} \right) = -2 \frac{d}{dz} U \Rightarrow \frac{d}{dz} \left[\left(\frac{d\varphi}{dz} \right)^2 + 2U \right] = 0 \Rightarrow \frac{1}{2} \left(\frac{d\varphi}{dz} \right)^2 + U = \text{cost}$$

$$\frac{d\varphi}{dz} = -\frac{\omega_{RF}}{cE_0 \beta_s^3 \gamma_s^3} w$$

$$\frac{1}{2} \left(\frac{\omega_{RF}}{cE_0 \beta_s^3 \gamma_s^3} \right)^2 w^2 + \frac{\omega_{RF} qE_{RF}}{cE_0 \beta_s^3 \gamma_s^3} [\sin(\phi_s + \varphi) - \varphi \cos\phi_s - \sin(\phi_s)] = \text{const} = H$$
