Hendrik A. Lorentz  
1853 – 1928

# Lorentz force

- A charged particle moving with velocity  $\vec{v} = \frac{\vec{p}}{m \gamma}$  through an electromagnetic field in vacuum experiences the Lorentz force  $\frac{d\vec{p}}{dt} = q(\vec{E} + \vec{v} \times \vec{B})$ .
- The total energy of this particle is  $W = \sqrt{(mc^2)^2 + (pc)^2} = \gamma mc^2$ , the kinetic energy is  $W_{kin} = mc^2(\gamma - 1)$ .
- The role of acceleration is to increase  $W$ .
- Change of  $W$  (by differentiation):

$$WdW = c^2 \vec{p} \cdot d\vec{p} = qc^2 \vec{p} \cdot (\vec{E} + \vec{v} \times \vec{B}) dt = qc^2 \vec{p} \cdot \vec{E} dt$$
$$dW = q\vec{v} \cdot \vec{E} dt$$

Note: **Only the electric field can change the particle energy!**

James Clerk Maxwell  
1831 – 1879

# Maxwell's equations in vacuum

Source-free:

$$\nabla \times \vec{B} - \frac{1}{c^2} \frac{\partial}{\partial t} \vec{E} = 0 \quad \nabla \cdot \vec{B} = 0$$

$$\nabla \times \vec{E} + \frac{\partial}{\partial t} \vec{B} = 0 \quad \nabla \cdot \vec{E} = 0$$

curl (rot,  $\nabla \times$ ) of 3<sup>rd</sup> equation and  $\frac{\partial}{\partial t}$  of 1<sup>st</sup> equation:

$$\nabla \times \nabla \times \vec{E} + \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \vec{E} = 0.$$

Using the vector identity  $\nabla \times \nabla \times \vec{E} = \nabla \nabla \cdot \vec{E} - \nabla^2 \vec{E}$  and the 4<sup>th</sup> Maxwell equation, this yields:

$$\nabla^2 \vec{E} - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \vec{E} = 0,$$

i.e. the 4-dimensional Laplace equation.

Photo:  
Reidar Hahn

# Homogeneous plane wave

$$\vec{E} \propto \vec{u}_y \cos(\omega t - \vec{k} \cdot \vec{r})$$

$$\vec{B} \propto \vec{u}_x \cos(\omega t - \vec{k} \cdot \vec{r})$$

$$\vec{k} \cdot \vec{r} = \frac{\omega}{c} (z \cos \varphi + x \sin \varphi)$$

**Wave vector  $\vec{k}$ :**  
 the direction of  $\vec{k}$  is the direction of propagation,  
 the length of  $\vec{k}$  is the phase shift per unit length.  
 $\vec{k}$  behaves like a vector.

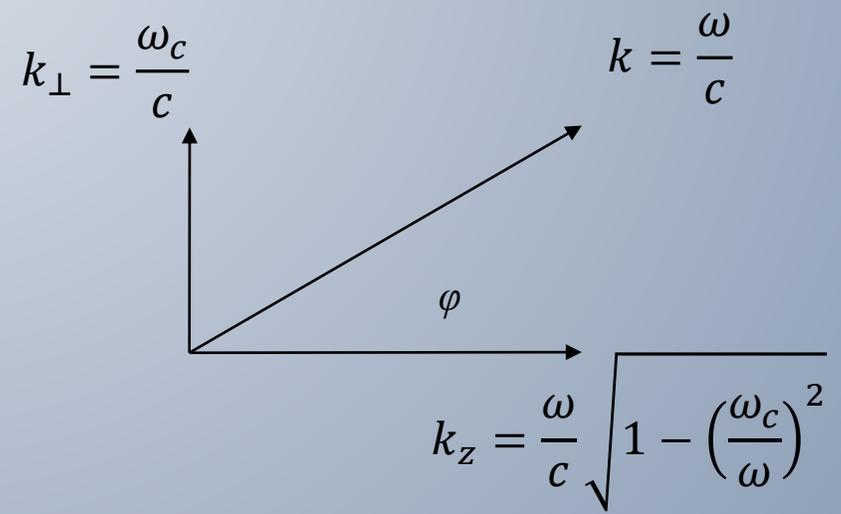

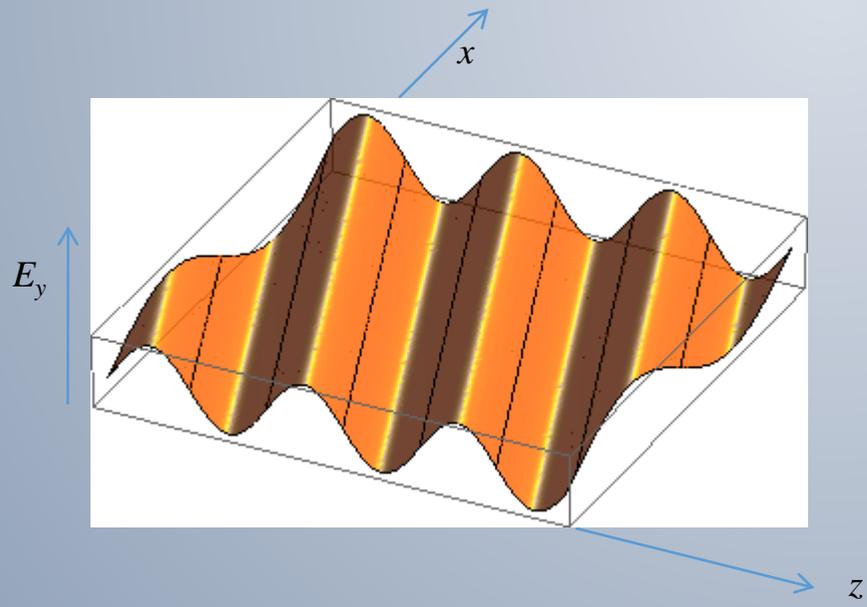

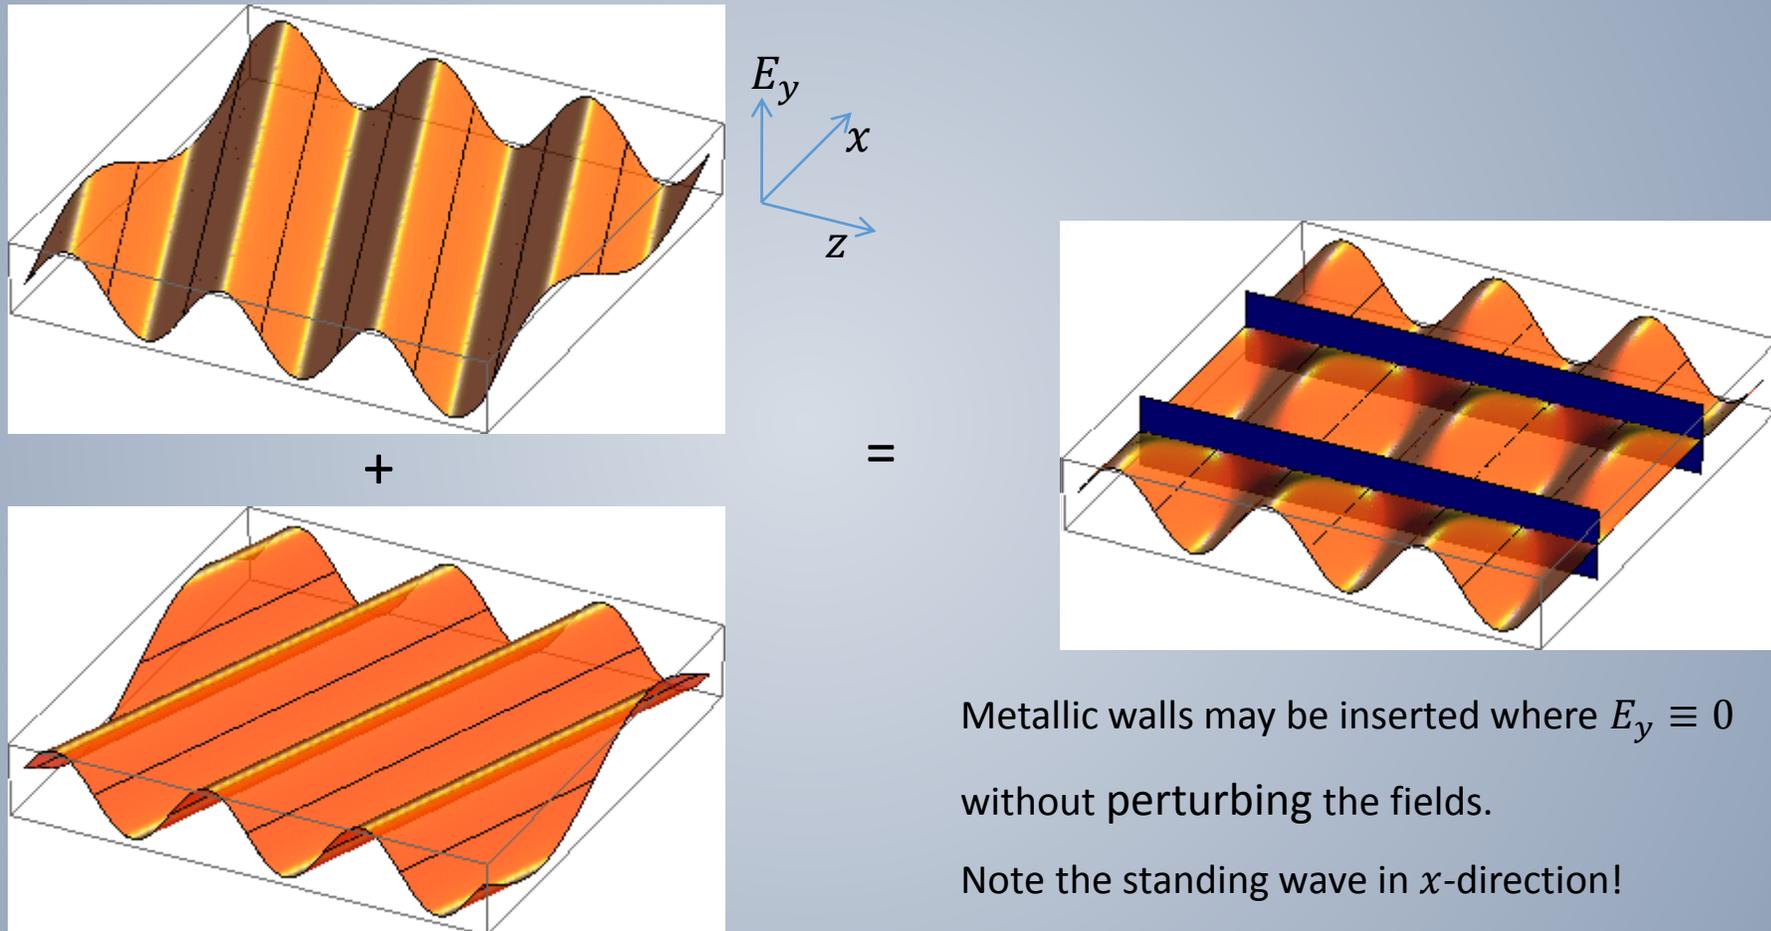

Photo:  
Reidar Hahn

# Superposition of 2 homogeneous plane waves

Metallic walls may be inserted where  $E_y \equiv 0$

without perturbing the fields.

Note the standing wave in  $x$ -direction!

This way one gets a hollow rectangular waveguide.

Photo:  
Reidar Hahn

# Rectangular waveguide

Fundamental ( $TE_{10}$  or  $H_{10}$ ) mode  
in a standard rectangular waveguide.

**Example 1:** "S-band": 2.6 GHz ... 3.95 GHz,

Waveguide type WR284 (2.84" wide), dimensions:  
72.14 mm x 34.04 mm.  
cut-off:  $f_c = 2.078$  GHz.

**Example 2:** "L-band" : 1.13 GHz ... 1.73 GHz,

Waveguide type WR650 (6.5" wide), dimensions:  
165.1 mm x 82.55 mm.  
cut-off:  $f_c = 0.908$  GHz.

Both these pictures correspond to operation at  $1.5 f_c$ .

$$\text{power flow: } \frac{1}{2} \text{Re} \left\{ \iint \vec{E} \times \vec{H}^* \cdot d\vec{A} \right\}$$

Reidar Hahn

# Waveguide dispersion – phase velocity $v_{\phi,z}$

The phase velocity  $v_{\phi,z}$  is the speed at which the crest (or zero-crossing) travels in  $z$ -direction.

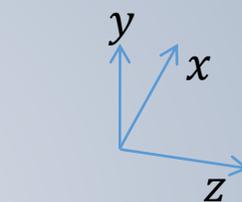

Note on the 3 animations on the right that, at constant  $f$ ,  $v_{\phi,z} \propto \lambda_g$ . Note also that at  $f = f_c$ ,  $v_{\phi,z} = \infty$ !

With  $f \rightarrow \infty$ ,  $v_{\phi,z} \rightarrow c$ !

cutoff:  $f_c = \frac{c}{2a}$ ,  $v_{\phi,z} = \infty$

1:  
 $a = 52 \text{ mm}$ ,  
 $f/f_c = 1.04$

2:  
 $a = 72.14 \text{ mm}$ ,  
 $f/f_c = 1.44$

3:  
 $a = 144.3 \text{ mm}$ ,  
 $f/f_c = 2.88$

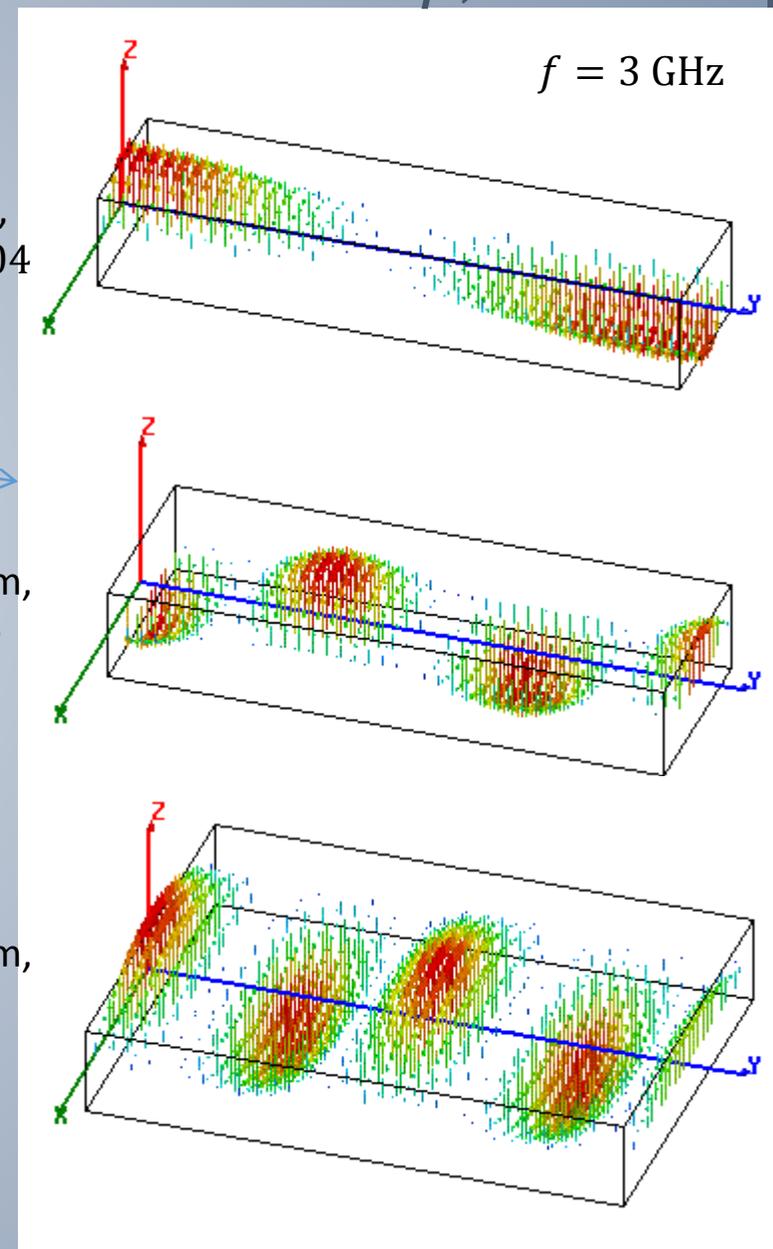

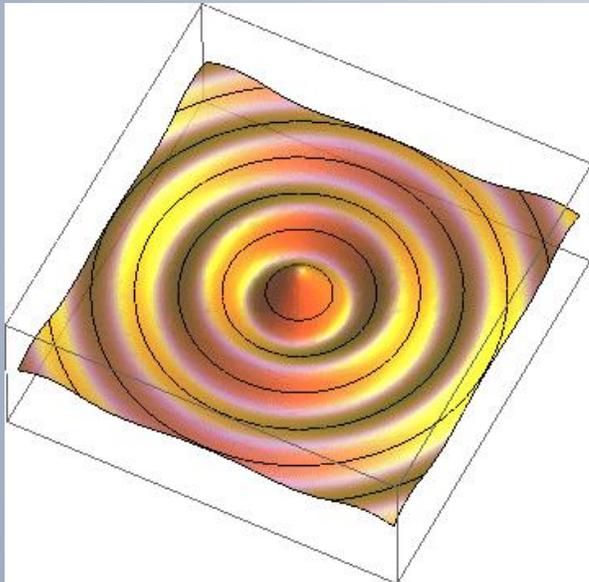

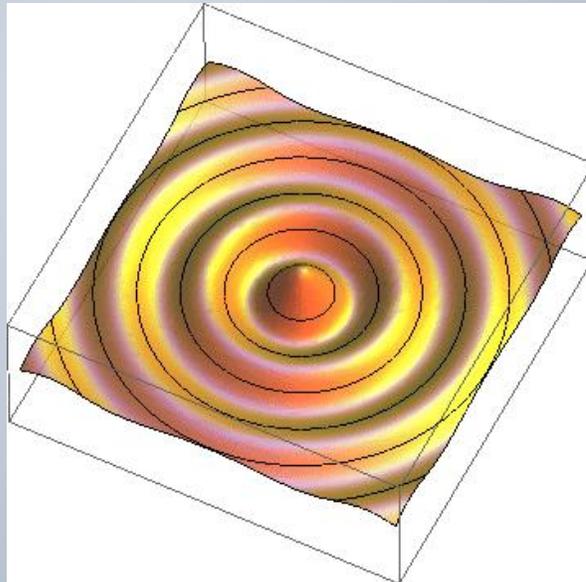

Photo:  
Reidar Hahn

# Radial waves

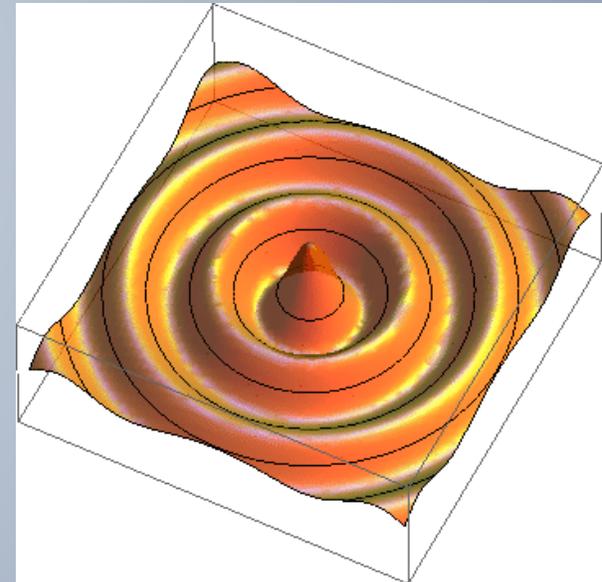

Also radial waves may be interpreted as superposition of plane waves. The superposition of an outward and an inward radial wave can result in the field of a round hollow waveguide.

$$E_z \propto H_n^{(2)}(k_\rho \rho) \cos(n\varphi)$$

$$E_z \propto H_n^{(1)}(k_\rho \rho) \cos(n\varphi)$$

$$E_z \propto J_n(k_\rho \rho) \cos(n\varphi)$$

# Acceleration voltage and $R/Q$

electric field

- I define

$$V_{acc} = \int_{-\infty}^{\infty} E_z e^{j\frac{\omega}{\beta c}z} dz.$$

- The exponential factor accounts for the variation of the field while particles with velocity  $\beta c$  are traversing the cavity gap.
- With this definition,  $V_{acc}$  is generally complex – this becomes important with more than one gap (cell).
- For the time being we are only interested in  $|V_{acc}|$ .
- The square of the acceleration voltage  $|V_{acc}|^2$  is proportional to the stored energy  $W$ ; the proportionality constant defines the quantity called “ $R$ -upon- $Q$ ”:

$$\frac{R}{Q} = \frac{|V_{acc}|^2}{2\omega_0 W}.$$

- › **Attention – different definitions are used in literature!**

Photo:  
Reidar Hahn

# Transit time factor

- The transit time factor is the ratio of the acceleration voltage to the (non-physical) voltage a particle with infinite velocity would see:

$$TT = \frac{|V_{acc}|}{|\int E_z dz|} = \frac{|\int E_z e^{j\frac{\omega}{\beta c}z} dz|}{|\int E_z dz|}$$

- The transit time factor of an ideal pillbox cavity (no axial field dependence) of height (gap length)  $h$  is:

$$TT = \frac{\sin\left(\frac{\chi_{01}h}{2a}\right)}{\frac{\chi_{01}h}{2a}}$$

(remember:  $\omega_0 = \frac{2\pi c}{\lambda} = \frac{\chi_{01}c}{a}$ )

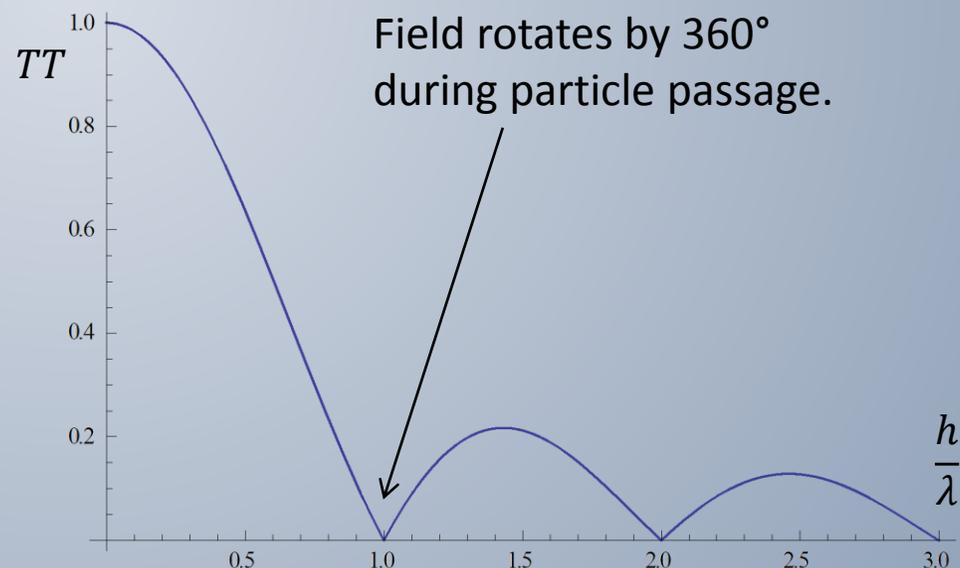

Photo:  
Reidar Hahn

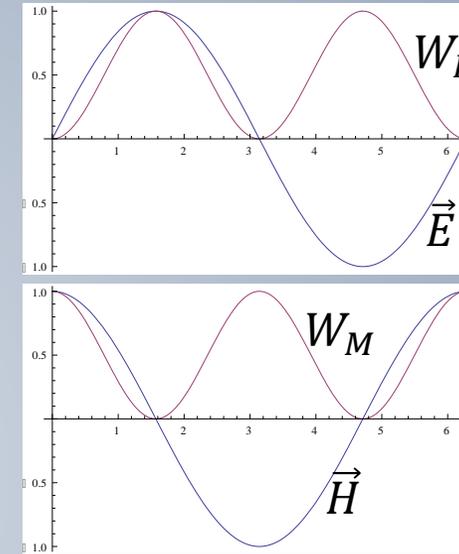

# Stored energy

- The energy stored in the electric field is

$$W_E = \iiint_{\text{cavity}} \frac{\epsilon}{2} |\vec{E}|^2 dV.$$

- The energy stored in the magnetic field is

$$W_M = \iiint_{\text{cavity}} \frac{\mu}{2} |\vec{H}|^2 dV.$$

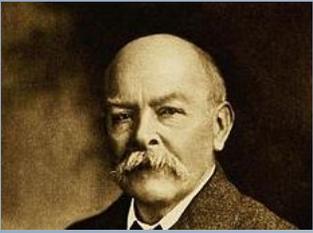

- Since  $\vec{E}$  and  $\vec{H}$  are  $90^\circ$  out of phase, the stored energy continuously swaps from electric energy to magnetic energy.
- On average, electric and magnetic energy must be equal.
- In steady state, the Poynting vector describes this energy flux.
- In steady state, the total energy stored (constant) is

$$W = \iiint_{\text{cavity}} \left( \frac{\epsilon}{2} |\vec{E}|^2 + \frac{\mu}{2} |\vec{H}|^2 \right) dV.$$

# Wall losses & $Q_0$

- The losses  $P_{\text{loss}}$  are proportional to the stored energy  $W$ .
- The tangential  $\vec{H}$  on the surface is linked to a surface current  $\vec{J}_A = \vec{n} \times \vec{H}$  (flowing in the skin depth  $\delta = \sqrt{2 / (\omega\mu\sigma)}$ ).
- This surface current  $\vec{J}_A$  sees a surface resistance  $R_s$ , resulting in a local power density  $R_s |H_t|^2$  flowing into the wall.
- $R_s$  is related to skin depth  $\delta$  as  $\delta\sigma R_s = 1$ .
  - Cu at 300 K has  $\sigma \approx 5.8 \cdot 10^7 \text{ S/m}$ , leading to  $R_s \approx 8 \text{ m}\Omega$  at 1 GHz, scaling with  $\sqrt{\omega}$ .
  - Nb at 2 K has a typical  $R_s \approx 10 \text{ n}\Omega$  at 1 GHz, scaling with  $\omega^2$ .
- The total wall losses result from  $P_{\text{loss}} = \iint_{\text{wall}} R_s |H_t|^2 dA$ .
- The cavity  $Q_0$  (caused by wall losses) is defined as  $Q_0 = \frac{\omega_0 W}{P_{\text{loss}}}$ .
- Typical  $Q_0$  values:
  - Cu at 300 K (normal-conducting):  $\mathcal{O}(10^3 \dots 10^5)$ , **should** improve at cryogenic  $T$  by a factor  $\sqrt{\rho_{RR}}$ .
  - Nb at 2 K (superconducting):  $\mathcal{O}(10^9 \dots 10^{11})$

No! Anomalous skin effect!

improves only by a factor  $\approx 10!$

Photo:  
Reidar Hahn

# Shunt impedance

- Also the power loss  $P_{\text{loss}}$  is also proportional to the square of the acceleration voltage  $|V_{\text{acc}}|^2$ ; the proportionality constant defines the “shunt impedance”

$$R = \frac{|V_{\text{acc}}|^2}{2 P_{\text{loss}}}.$$

- › **Attention, also here different definitions are used!**
- Traditionally, the shunt impedance is the quantity to optimize in order to minimize the power required for a given gap voltage.
- Now the previously introduced term “ $R$ -upon- $Q$ ” makes sense:

$$\left(\frac{R}{Q}\right) = R/Q$$

Photo:  
Reidar Hahn

# Geometric factor

- With

$$Q_0 = \frac{\omega_0 W}{\iint_{wall} R_s |H_t|^2 dA},$$

and assuming an average surface resistance  $R_s$ , one can introduce the “geometric factor”  $G$  as

$$G = Q_0 \cdot R_s = \frac{\omega_0 W}{\iint_{wall} |H_t|^2 dA}.$$

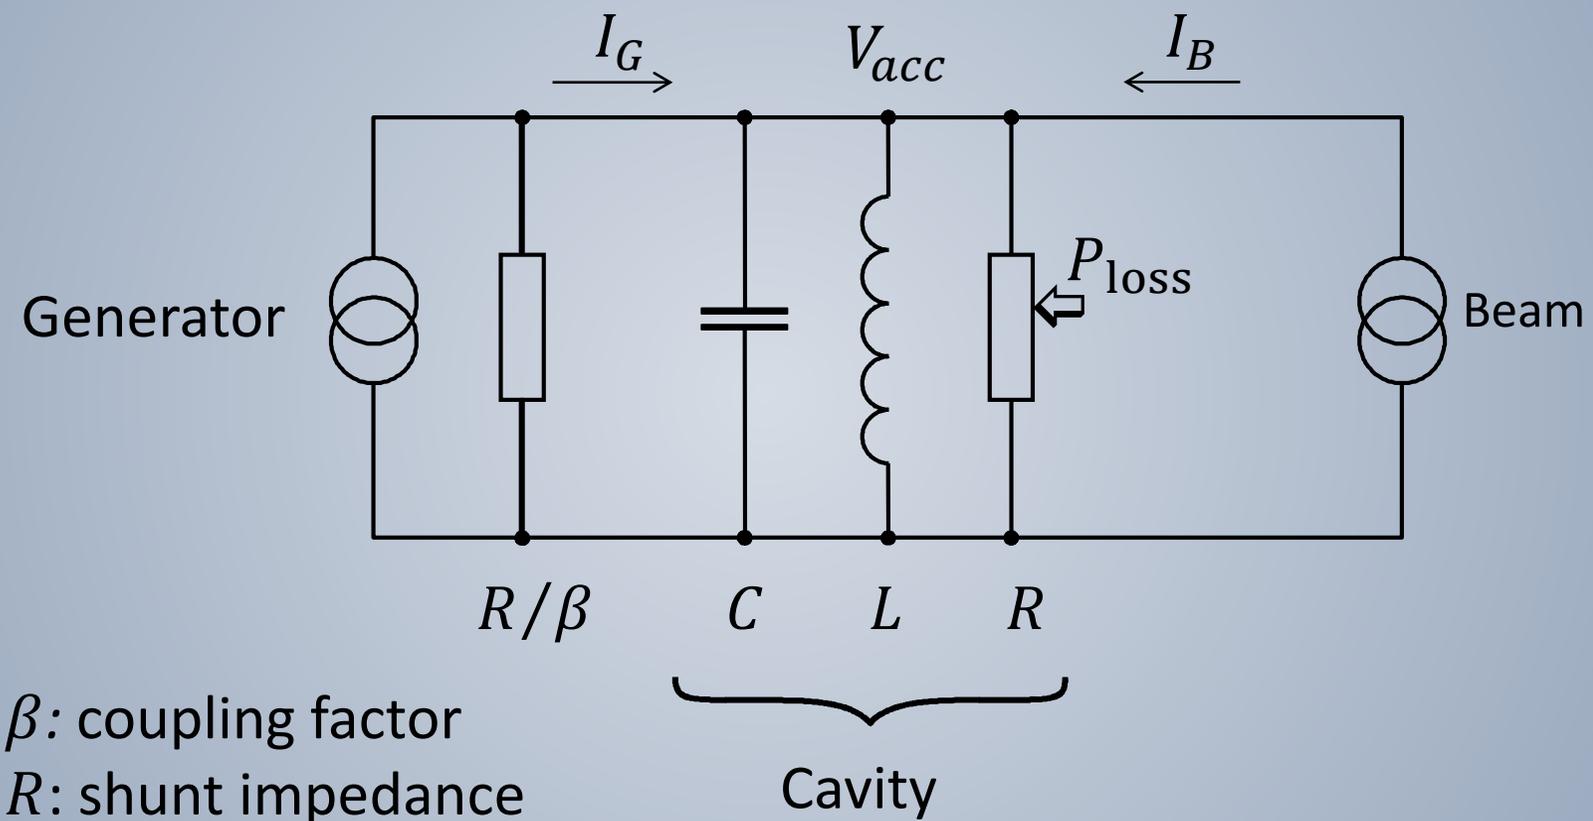

- $G$  has dimension Ohm, depends only on the cavity geometry (as the name suggests) and typically is  $\mathcal{O}(100 \Omega)$ .
- Note that  $R_s \cdot R = G \cdot (R/Q)$  (dimension  $\Omega^2$ , purely geometric)
- $G$  is only used for SC cavities.

Photo:  
Reidar Hahn

# Cavity resonator – equivalent circuit

Simplification: single mode

$\beta$ : coupling factor  
 $R$ : shunt impedance  
 $\sqrt{L/C} = \frac{R}{Q}$ : R-upon-Q

Photo:  
Reidar Hahn

# Power coupling - Loaded $Q$

- Note that the generator inner impedance also loads the cavity – for very large  $Q_0$  more than the cavity wall losses.
- To calculate the loaded  $Q$  ( $Q_L$ ), losses have to be added:

$$\frac{1}{Q_L} = \frac{P_{\text{loss}} + P_{\text{ext}} + \dots}{\omega_0 W} = \frac{1}{Q_0} + \frac{1}{Q_{\text{ext}}} + \frac{1}{\dots}$$

- The coupling factor  $\beta$  is the ratio  $P_{\text{ext}}/P_{\text{loss}}$ .
- With  $\beta$ , the loaded  $Q$  can be written

$$Q_L = \frac{Q_0}{1 + \beta}$$

- For NC cavities, often  $\beta = 1$  is chosen (power amplifier matched to empty cavity); for SC cavities,  $\beta = \mathcal{O}(10^4 \dots 10^6)$ .

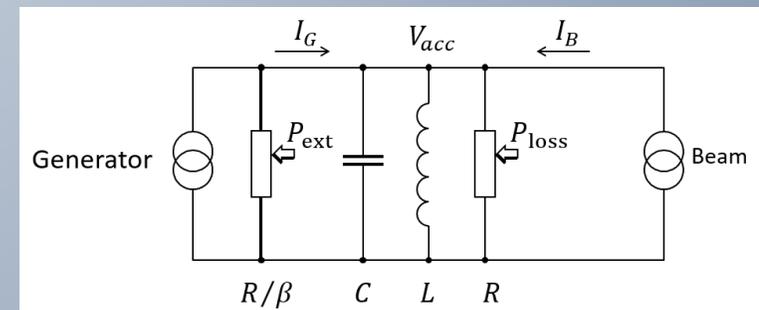

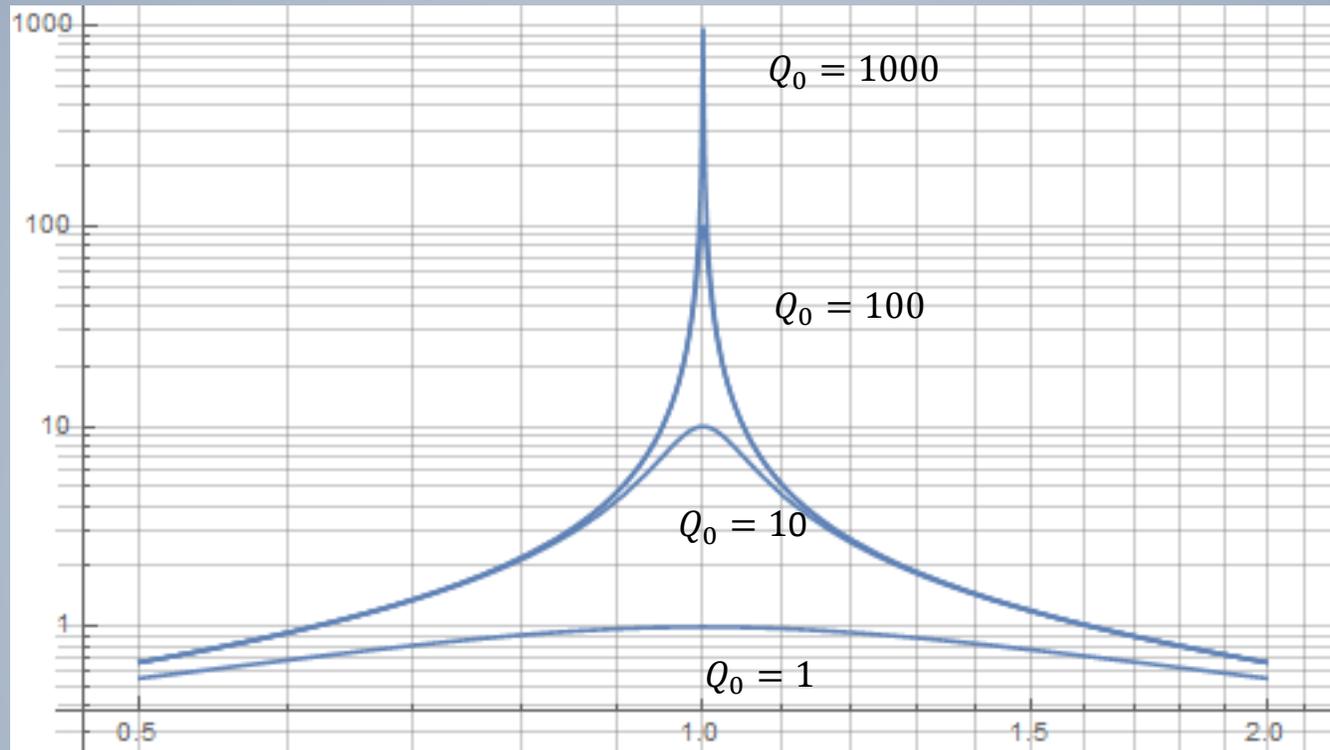

Photo:  
Reidar Hahn

# Resonance

$$\frac{Z(\omega)}{R/Q}$$

$$\frac{\omega}{\omega_0}$$

- While a high  $Q_0$  results in small wall losses, so less power is needed for the same voltage.
- On the other hand the bandwidth becomes very narrow.
- Note: a 1 GHz cavity with a  $Q_0$  of  $10^{10}$  has a natural bandwidth of 0.1 Hz!
- ... to make this manageable,  $Q_{ext}$  is chosen much smaller!

Photo:  
Reidar Hahn

# Summary: relations $V_{acc}$ , $W$ and $P_{loss}$

Attention – different definitions are used in literature !

$V_{acc}$   
Accelerating voltage

$$\frac{R}{Q} = \frac{|V_{acc}|^2}{2\omega_0 W}$$

$$k_{loss} = \frac{\omega_0 R}{2 Q} = \frac{|V_{acc}|^2}{4W}$$

$$R = \frac{|V_{acc}|^2}{2P_{loss}} = \frac{R}{Q} Q_0$$

$W$   
Energy stored

$P_{loss}$   
wall losses

$$Q_0 = \frac{\omega_0 W}{P_{loss}}$$

Photo:  
Reidar Hahn

# Beam loading

- The beam current “loads” the cavity, in the equivalent circuit this appears as an impedance in parallel to the shunt impedance.
- If the generator is matched to the unloaded cavity ( $\beta = 1$ ), beam loading will (normally) cause the accelerating voltage to decrease.
- The power absorbed by the beam is  $-\frac{1}{2} \Re\{V_{acc} I_B^*\}$ .
- For high power transfer efficiency RF  $\rightarrow$  beam, beam loading must be high!
- For SC cavities (very large  $\beta$ ), the generator is typically matched to the beam impedance!
- Variation in the beam current leads to **transient beam loading**, which requires special care!
- Often the “impedance” the beam presents is strongly reactive – this leads to a detuning of the cavity.

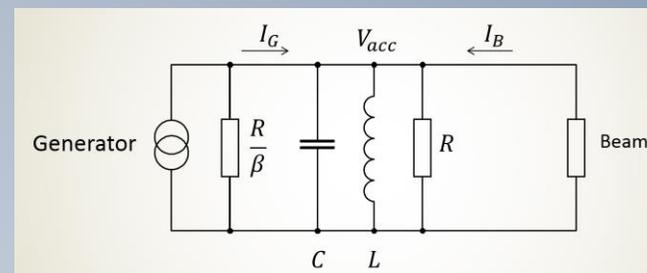

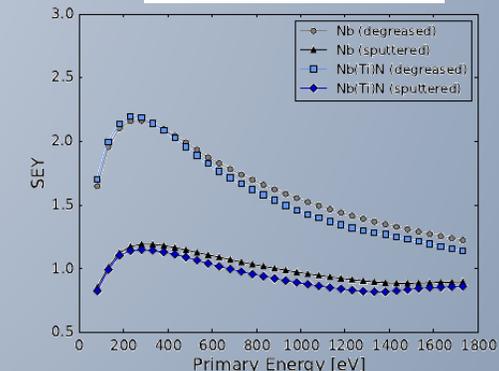

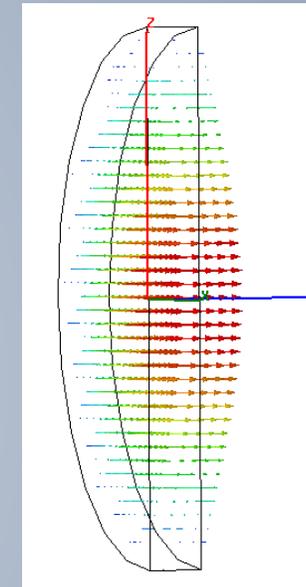

Photo:  
Reidar Hahn

# Multipactor

- The words “multipactor”, “to multipact” and “multipacting” are artificially composed of “multiple” “impact”.
- Multipactor describes a resonant RF phenomenon in vacuum:
  - Consider a free electron in a simple cavity – it gets accelerated by the electric field towards the wall
  - when it impacts the wall, secondary electrons will be emitted, described by the secondary emission yield (SEY)
  - in certain impact energy ranges, more than one electron is emitted for one electron impacting! So the number of electrons can increase
  - When the time for an electron from emission to impact takes exactly  $\frac{1}{2}$  of the RF period, resonance occurs – with the  $SEY > 1$ , this leads to an avalanche increase of electrons, effectively taking all RF power at this field level, depleting the stored energy and limiting the field!
- For this simple “2-point MP”, this resonance condition is reached at  $\frac{1}{4\pi m} e V = (fd)^2$  or  $\frac{V}{112 V} = \left(\frac{f}{\text{MHz}} \frac{d}{\text{m}}\right)^2$ . There exist other resonant bands.

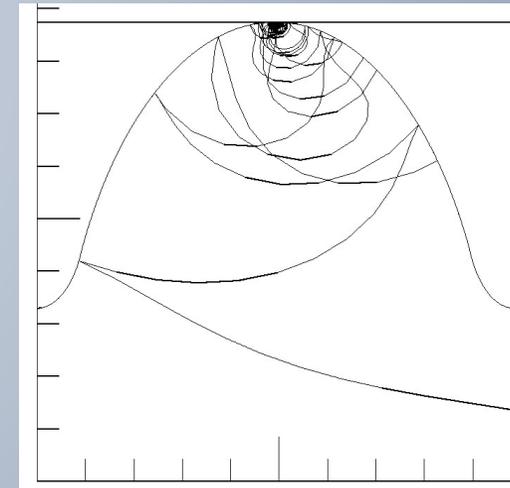

courtesy: Sarah Aull/CERN

# Multipactor (contd.)

- Unfortunately, good metallic conductors (Cu, Ag, Nb) all have  $SEY > 1$ !
- 1-point MP occurs when the electron impact where they were emitted
- Electron trajectories can be complex since both  $\vec{E}$  and  $\vec{B}$  influence them; computer simulations allow to determine the MP bands (barriers)
- To reduce or suppress MP, a combination of the following may be considered:
  - Use materials with low SEY
  - Optimize the shape of your cavity ( $\rightarrow$  elliptical cavity)
  - Conditioning (surface altered by exposure to RF fields)
  - Coating (Ti, TiN, NEG, amorphous C ...)
  - Clearing electrode (for a superimposed DC electric field)
  - Rough surfaces

Many gaps

Photo:  
Reidar Hahn

# What do you gain with many gaps?

- The  $R/Q$  of a single gap cavity is limited to some  $100 \Omega$ .  
Now consider to distribute the available power to  $n$  identical cavities: each will receive  $P/n$ , thus produce an accelerating voltage of  $\sqrt{2RP/n}$ . (Attention: phase important!)  
The total accelerating voltage thus increased, equivalent to a total equivalent shunt impedance of  $nR$ .

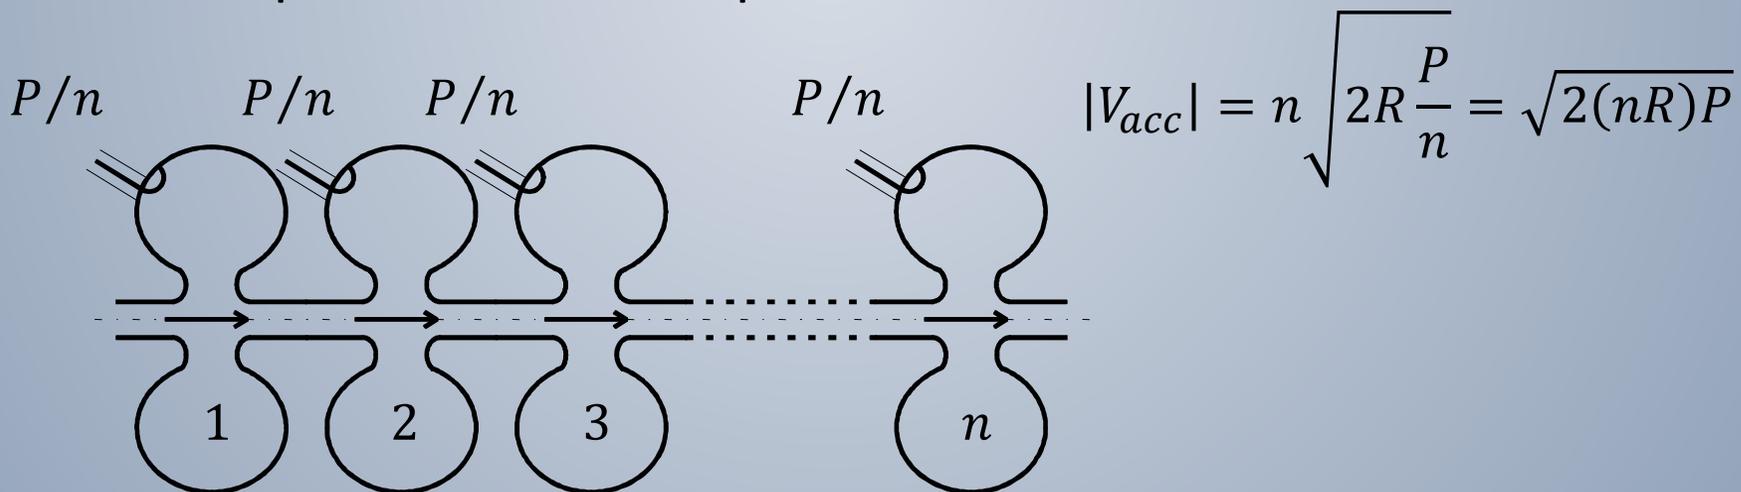

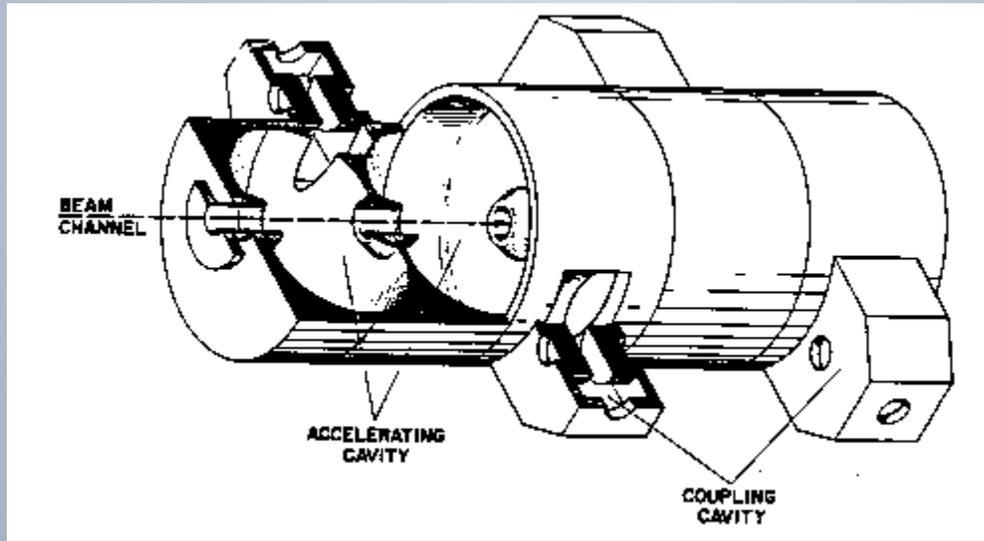

Photo:  
Reidar Hahn

# Standing wave multi-cell cavity

- Instead of distributing the power from the amplifier, one might as well couple the cavities, such that the power automatically distributes, or have a cavity with many gaps (e.g. drift tube linac).
- Coupled cavity accelerating structure (side coupled)

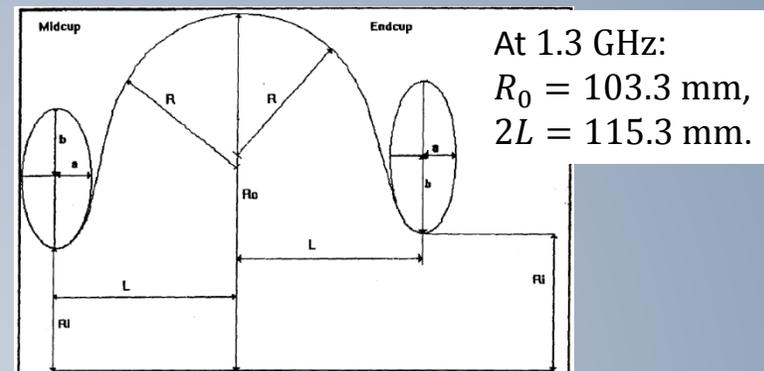

- The phase relation between gaps is important!

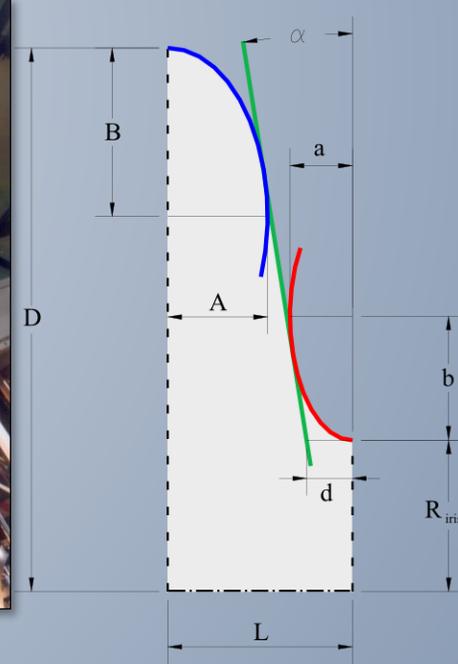

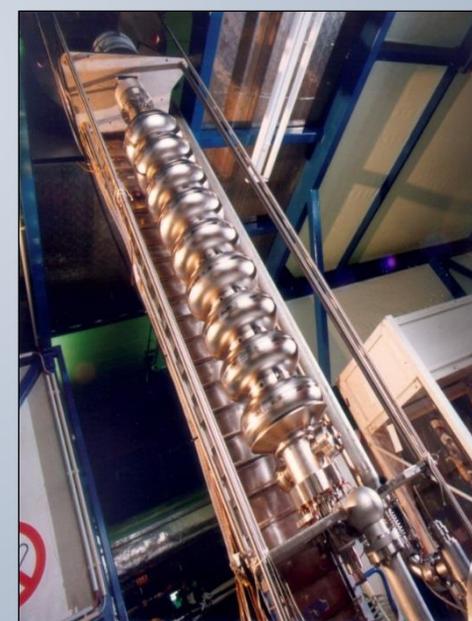

Photo:  
Reidar Hahn

# The elliptical cavity

- The elliptical shape was found as optimum compromise between
  - maximum gradient ( $E_{acc}/E_{surface}$ )
  - suppression of multipactor
  - mode purity
  - machinability
- A multi-cell elliptical cavity is typically operated in  $\pi$ -mode, i.e. cell length is exactly  $\beta\lambda/2$ .
- It has become de facto standard, used for ions and leptons! E.g.:
  - ILC/X-FEL: 1.3 GHz, 9-cell cavity
  - SNS (805 MHz)
  - SPL/ESS (704 MHz)
  - LHC (400 MHz)

Paul Drude  
1863 – 1906

# How does electrical conduction work?

- Drude model: In a conductor, the electrons move through an ion lattice, bounce off the ions and get slowed in the process.
- In the presence of  $E$  fields only, this is governed by the equation

$$\frac{d}{dt}p = eE - p/\tau.$$

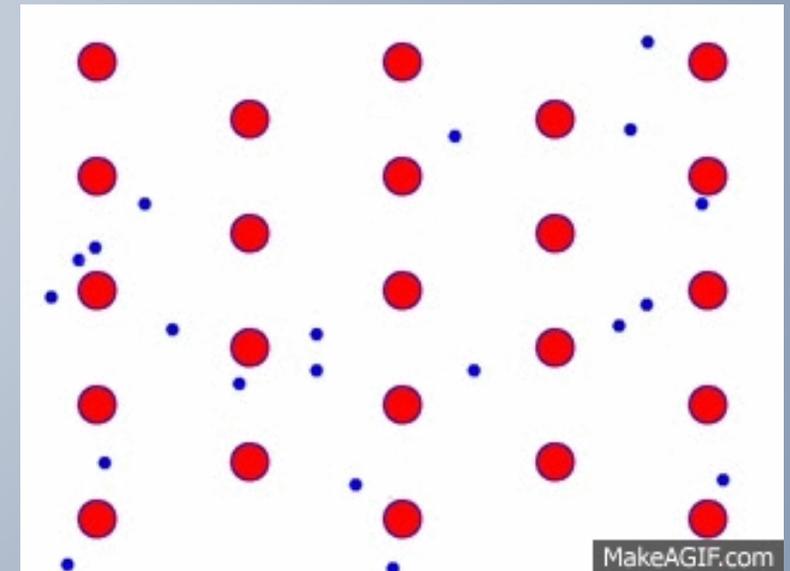

- In steady state (DC), one gets

$$v = \frac{e}{m} \tau E, \text{ which is ...}$$

- ... Ohm's law:  $j_n = nev = \frac{e^2 \tau n}{m} E = \sigma E$

$$\text{with } \sigma_{DC} = \frac{e^2 \tau n}{m}.$$

- Typical scattering time  $\tau \approx 10^{-14}$  s.

The electrons (blue) slowly drift to the right under the influence of a DC electric field

Photo:  
Reidar Hahn

## Drude model extended for RF

- The equation  $\frac{d}{dt}p = eE - \frac{p}{\tau}$  can of course be solved for an excitation by a time-varying field  $E = \Re\{\hat{E} e^{j\omega t}\}$ .
- Solution: Assume  $p(t)$  to be of the same time-dependence as RHS:  $p(t) = \Re\{\hat{p}e^{j\omega t}\}$  and solve:
  - $$\left(j\omega + \frac{1}{\tau}\right)\hat{p} = e\hat{E} \quad \text{or} \quad \hat{p} = \frac{\tau e\hat{E}}{1+j\omega\tau}.$$
- This naturally results in a complex,  $f$ -dependent  $\sigma$ :
$$\sigma = \sigma_{DC} \frac{1}{1+j\omega\tau} = \frac{\sigma_{DC}}{1+(\omega\tau)^2} (1-j\omega\tau)$$
- With  $\tau \approx 10^{-14}$ s,  $\omega\tau < 1$  for frequencies up to many THz!

Photo:  
Reidar Hahn

# Good (normal-)conductor boundary – skin depth

- A good (normal-)conductor: inside the metal, the surface field  $H_{\parallel}$  gives rise to a damped “wave”, which “propagates” into the metal with a propagation constant of  $k_{\perp} = \sqrt{-j\omega\mu\sigma}$ . The skin-depth is the inverse of the damping constant, the real part of  $k_{\perp}$ :

- **Skin depth:** 
$$\delta = \frac{1}{\alpha} = \frac{1}{\Re\{\sqrt{-j\omega\mu\sigma}\}} = \sqrt{\frac{2}{\omega\mu\sigma}}$$

- The wave impedance in the metal is  $Z = \sqrt{\frac{j\omega\mu}{\sigma}}$ , its real part

$R_n = \sqrt{\frac{\omega\mu}{2\sigma}}$  is the **surface resistance** and can be used to determine the losses.

$$\delta R_n \sigma \equiv 1$$

I use the term  $R_n$  for the surface resistance for normal conductors,  $R_s$  for superconductors.

Photo:  
Reidar Hahn

# Temperature dependence of resistivity of metals

$$\rho(T) = \frac{1}{\sigma(T)} = \rho_0 + A \left( \frac{T}{\Theta_D} \right)^5 \int_0^{\frac{\Theta_D}{T}} \frac{x^5}{(e^x - 1)(1 - e^{-x})} dx$$

Cu resistivity vs.  $T$ , assuming  
 $\rho(20^\circ\text{C}) = 16.78 \text{ n}\Omega\text{m}$ ,  
 $RRR = 300$  and  
 $\Theta_D = 343.5 \text{ K}$  (Debye  $T$ ).  
[Bloch-Grüneisen formula]

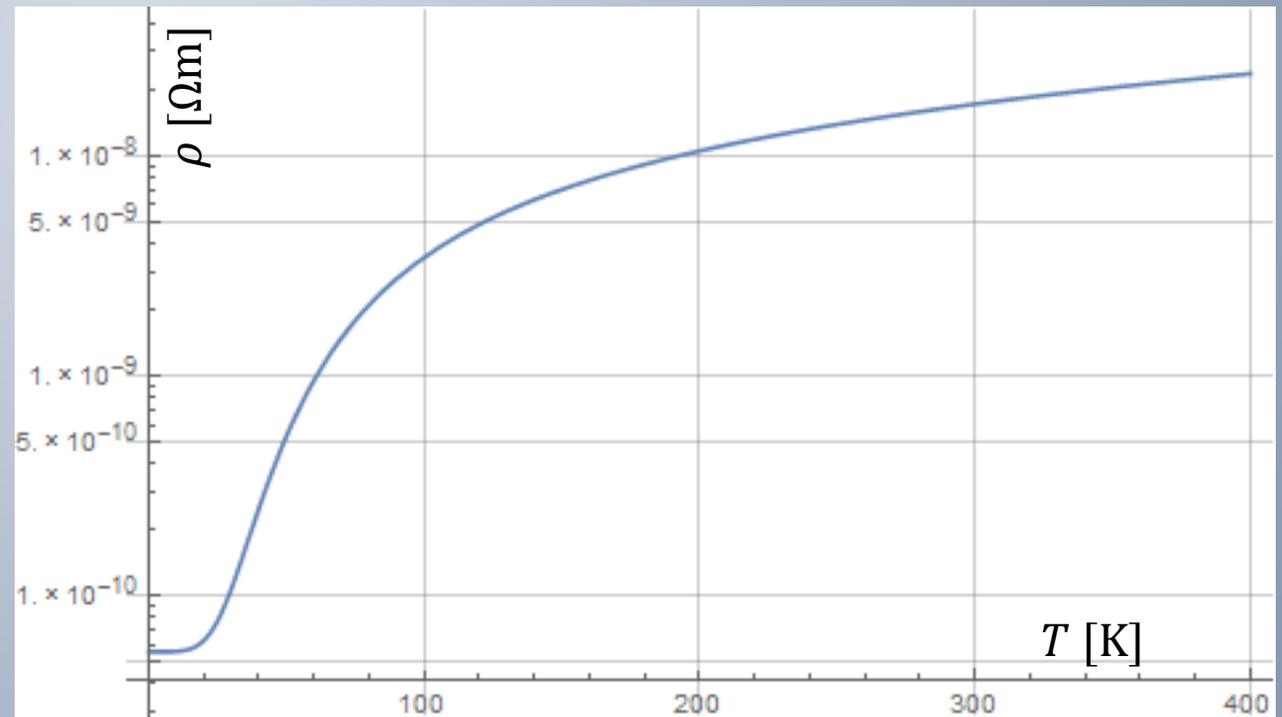

Photo:  
Reidar Hahn

# Anomalous skin effect

- The relation between skin depth  $\delta$  and surface resistance  $R_n$ ,  $\delta R_n \sigma \equiv 1$ , is valid only while the mean free path  $\ell$  of the electrons is smaller than the skin depth,  $\ell \ll \delta$ .
- If the skin depth gets smaller (e.g. at low  $T$ , high  $\omega$ ),  $R_n$  will be dominated by  $\ell$  and be limited to

$$R_n \approx \left( \sqrt{3} \pi \left( \frac{\ell}{\sigma} \right) \left( \frac{\mu \omega}{4 \pi} \right)^2 \right)^{1/3}$$

Prediction of surface resistance  $R_n(T)$  of Cu at 400 MHz with  $RRR = 300$  (blue) and correction for anomalous skin effect ( $\rho \ell = 6.6 \cdot 10^{-18} \Omega \text{m}^2$ ) (orange).

# Critical temperatures of superconductors

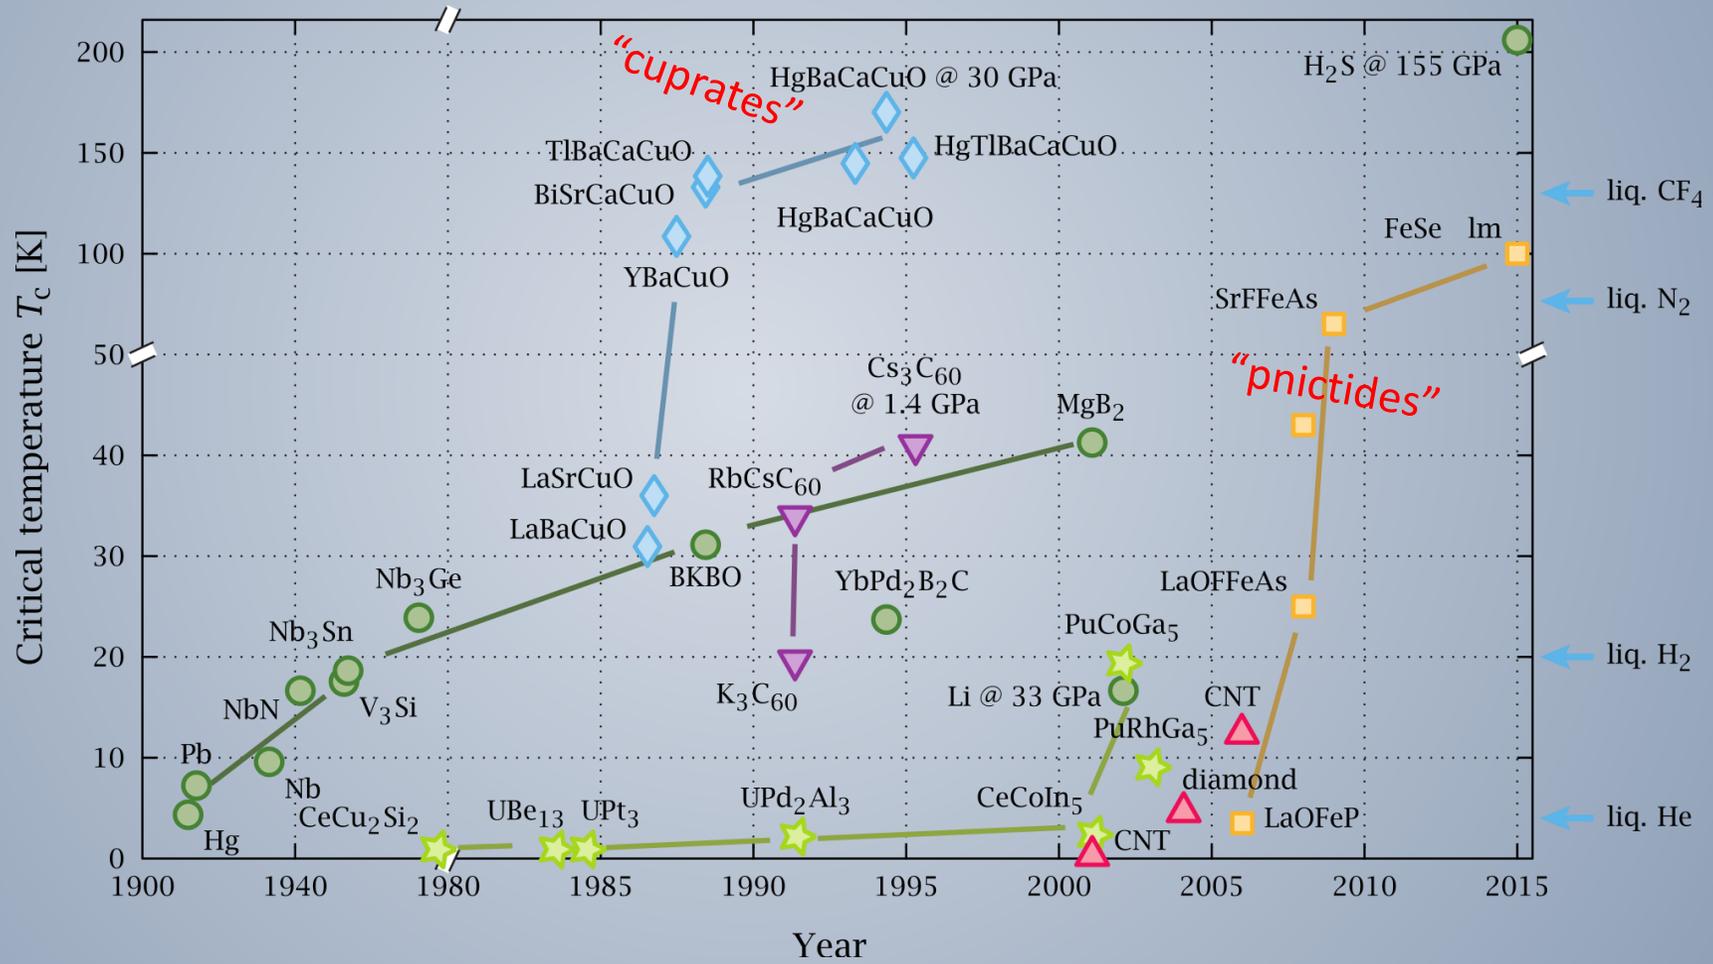

Photo:  
Reidar Hahn

# Phase diagram of a SC

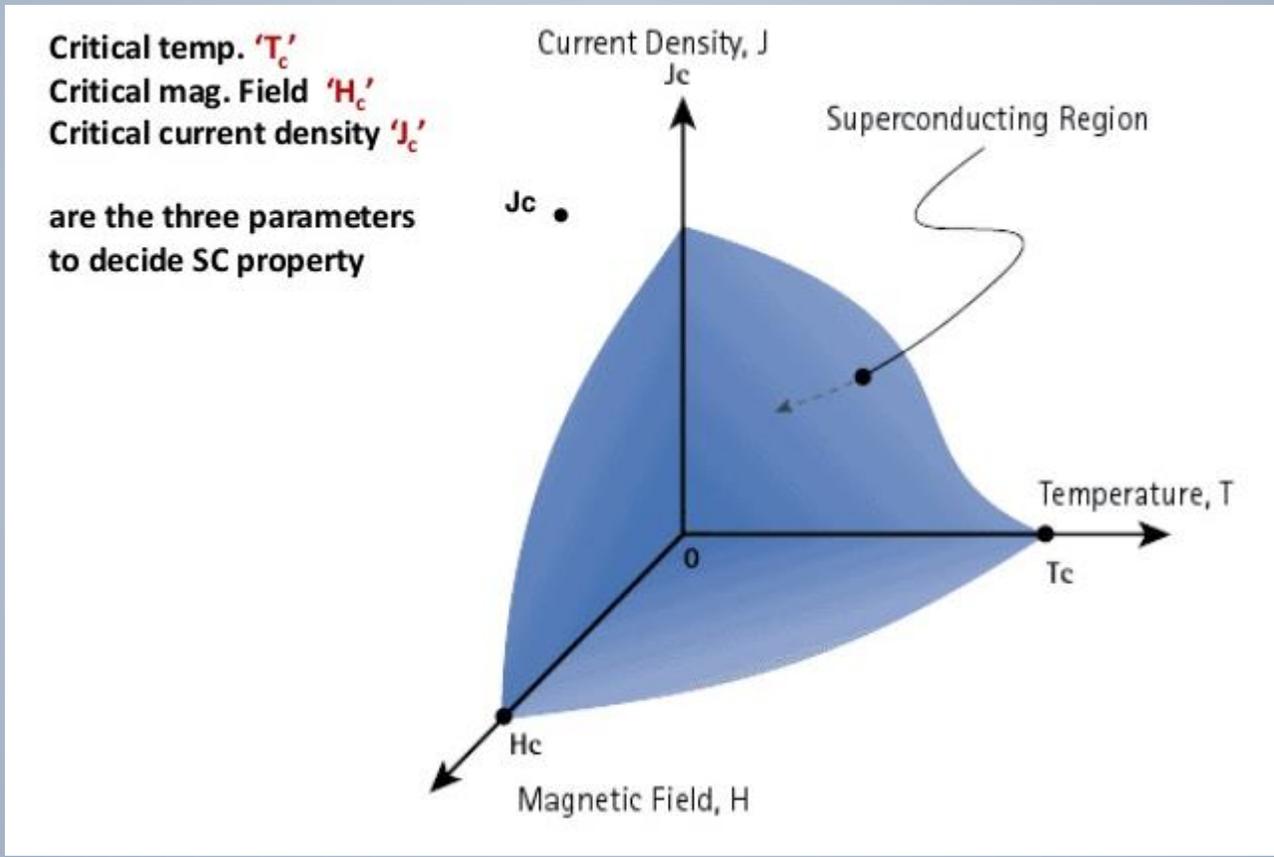

Photo:  
Reidar Hahn

# Perfect conductor

- With a magnetic field  $B_0$  at the transition vacuum/superconductor, the following equations hold:

- 3<sup>rd</sup> Maxwell equation:  $\nabla \times \vec{E} = -\frac{\partial \vec{B}}{\partial t}$

- 1<sup>st</sup> London equation:  $\frac{\partial \vec{j}_s}{\partial t} = \frac{n_s e^2}{m} \vec{E}$ , where  $\vec{j}_s = -n_s e \vec{v}$ .

- This results in the equation  $\frac{\partial}{\partial t} \left( \nabla \times \vec{j}_s + \frac{n_s e^2}{m} \vec{B} \right) = 0$ , or (slightly transformed) in  $\frac{\partial}{\partial t} \left( \nabla^2 \vec{B} - \mu \frac{n_s e^2}{m} \vec{B} \right) = 0$

- This could be solved by either a time-independent field,  $\frac{\partial}{\partial t} \equiv 0$  or by a field satisfying  $\nabla^2 \vec{B} - \mu \frac{n_s e^2}{m} \vec{B} = 0$ .  
 $\mu \frac{n_s e^2}{m} = \lambda_L^{-2}$

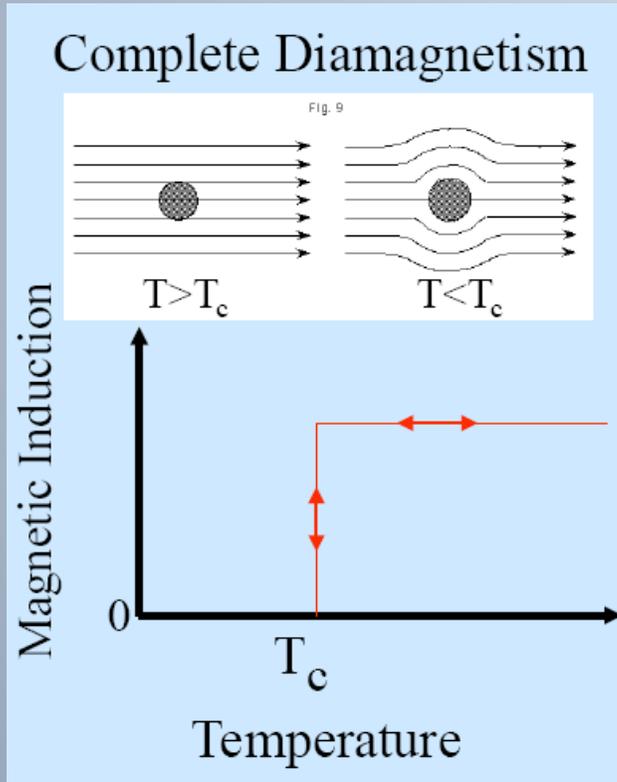

Photo:  
Reidar Hahn

# Meissner effect (flux expulsion)

Walther Meißner  
1882 – 1974

- Observation: During cool-down, when  $T$  passes  $T_c$ , the magnetic field gets completely expelled.

- A non-vanishing, time-independent field is not observed and thus can be excluded as non-physical.

Photo:  
Reidar Hahn

# London equations

London brothers  
Heinz (1907 – 1970),  
Fritz (1900 – 1954)

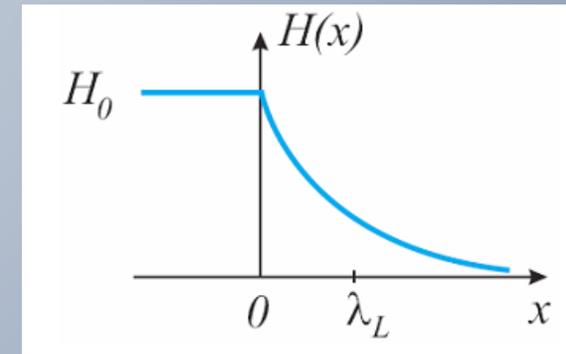

- Supported by Meissner's observation, the time-independent (non-trivial) solution of the equation

$$\frac{\partial}{\partial t} \left( \nabla \times \vec{j}_s + \frac{n_s e^2}{m} \vec{B} \right) = 0 \text{ can be excluded as non-physical.}$$

- London equations (London penetration depth:  $\lambda_L = \sqrt{\frac{m}{\mu n_s e^2}}$ )

1. (zero resistance):  $\frac{\partial \vec{j}_s}{\partial t} = \frac{n_s e^2}{m} \vec{E} = \frac{1}{\mu \lambda_L^2} \vec{E}$

2. (Meissner effect):  $\nabla \times \vec{j}_s + \frac{n_s e^2}{m} \vec{B} = 0$   
or  $\left( \nabla^2 - \frac{1}{\lambda_L^2} \right) \vec{B} = 0$

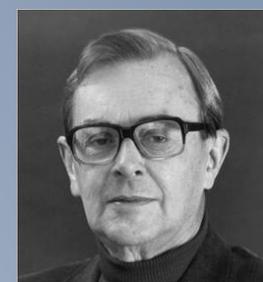

vacuum | superconductor

Photo:  
Reidar Hahn

# The coherence length $\xi$

Brian Pippard  
1920 – 2008

- Pippard found out that  $\lambda_L$  depends on the purity of the material and therefore on the electron mean free path  $\ell$ .
- In 1953, he proposed the coherence length  $\xi$  as a new parameter to better describe the characteristic dimension of the electrons wave function in a superconductor.

- In a pure metal, one finds  $\xi = \xi_0 \propto \frac{\hbar v_F}{k T_C}$ ,  
with impurities one can approximate  $\xi = \left(\frac{1}{\xi_0} + \frac{1}{\ell}\right)^{-1}$  and  $\lambda(\ell) = \lambda_L \sqrt{\frac{\xi_0}{\xi}}$ .
- “Clean” limit:  $\ell \gg \xi$ , “dirty” limit:  $\ell \ll \xi$ .

Photo:  
Reidar Hahn

## Characteristic lengths:

- London penetration depth  $\lambda_L = \sqrt{\frac{m}{\mu n_s e^2}}$ : the distance up to which magnetic field penetrates into a superconductor if placed in a magnetic field
- Electron mean free path  $\ell$ . ...gets smaller with impurities.
- Coherence length  $\xi = \left(\frac{1}{\xi_0} + \frac{1}{\ell}\right)^{-1}$ : the distance over which the electron wave function extends – the “size” of Cooper pairs (see below).
- Orders of magnitude:
  - $\lambda_L$  and  $\xi$ : tens of nm. (E.g. Nb:  $\xi_0 = 39$  nm, Pb:  $\xi_0 = 83$  nm)
  - $\ell$ : nm (dirty) to  $\mu\text{m}$  (clean)
- Sometimes used:  $\kappa \equiv \lambda_L / \xi$

# BCS Theory

Bardeen – Cooper – Schrieffer (BCS)

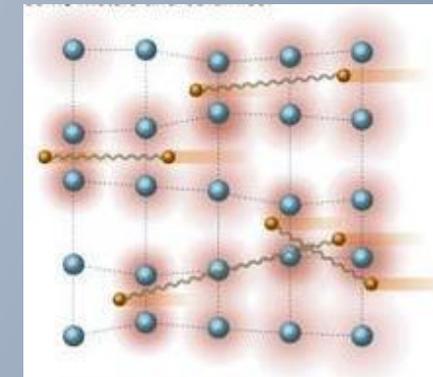

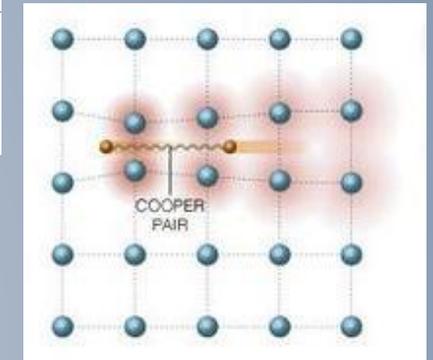

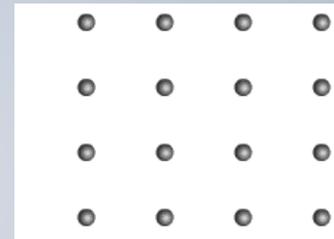

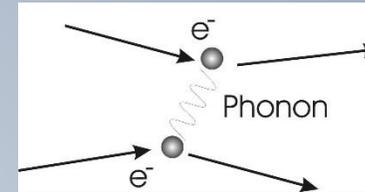

In 1958, Bardeen, Cooper and Schrieffer proposed a theory of superconductivity in which there exists an attractive interaction between electrons, forming “Cooper pairs”.

Photo:  
Reidar Hahn

# Cooper pairs

- Positively charged wake due to moving electron attracting nearby atoms (electron-phonon interaction)
- ... this wake can attract another nearby electron and ...
- → ... a Cooper pair is formed.
- Cooper pairs are formed by electrons with opposite momentum and spin.
- Cooper pairs belong all to the same quantum state and have the same energy.
- While electrons are fermions, Cooper pairs are bosons.
- When carrying a current, each Cooper pair acquires a momentum which is the same for all pairs,
- The **total** momentum of the pair remains constant. It can be changed only if the pair is broken, but this requires a minimum energy  $\Delta E$ .
- While NC electrons are scattered by the ion lattice (cf. Drude model) leading to resistive losses, Cooper pairs are not scattered by ion lattice.

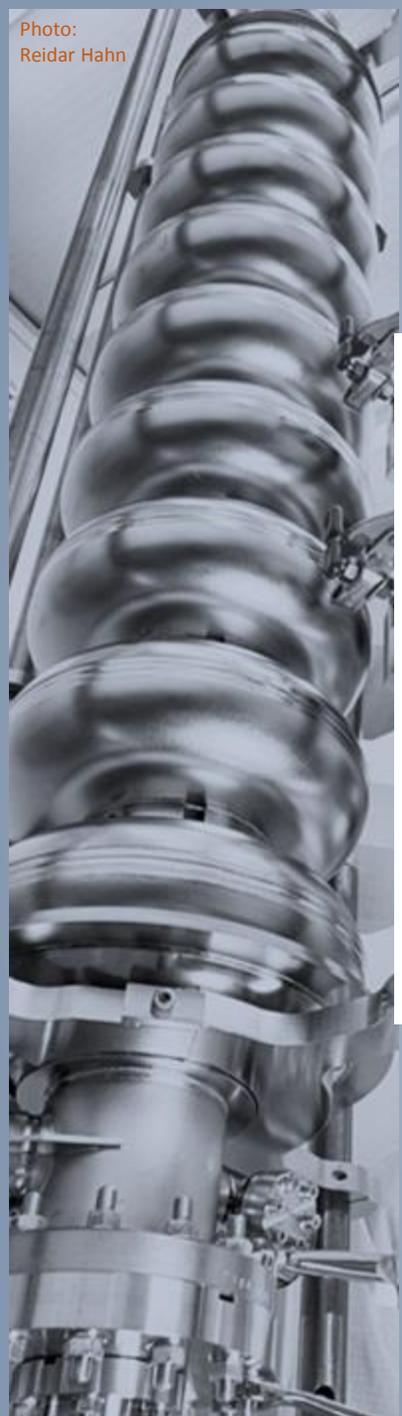

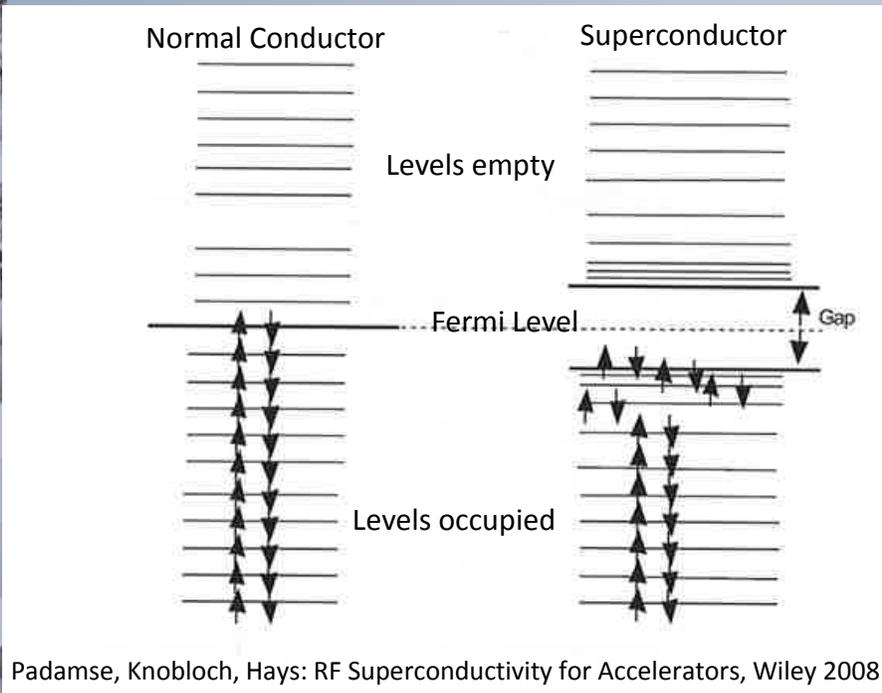

Photo:  
Reidar Hahn

# Energy gap

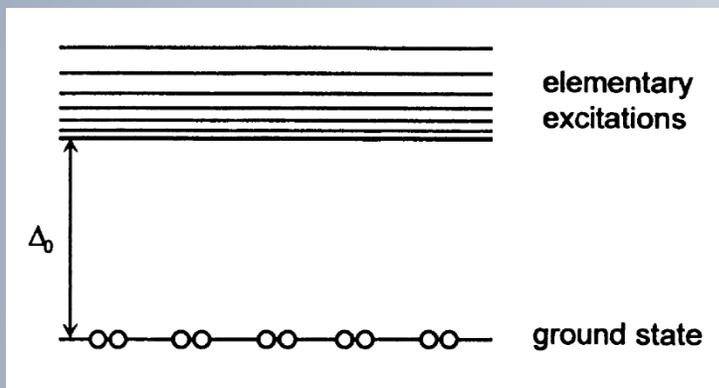

- The electron-phonon interaction changes the density of states.
- Near the Fermi surface an energy gap forms and energy states below get denser – the new ground state (with Cooper-pairs) has a lower energy than the NC ground state.
- For Nb,  $\Delta(0)/(k_B T_c) = 1.9$ , for Pb,  $\Delta(0)/(k_B T_c) = 2.4$ .

Reidar Hahn

# The microscopic BCS theory

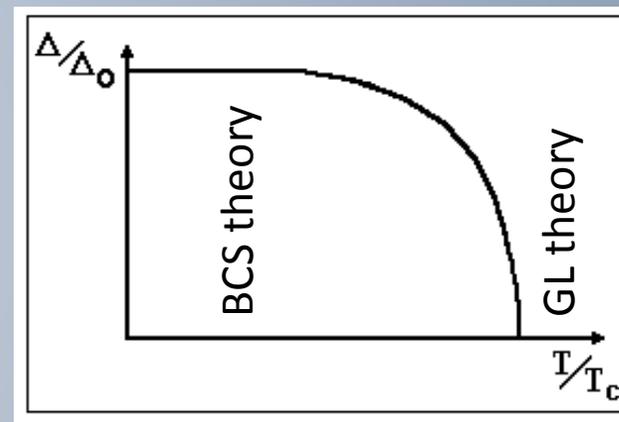

- The superconducting state consists of electron pairs and elementary excitations, quasiparticles, behaving almost as free electrons

The energy gap  $\Delta$  separates the energy levels of elementary excitations from the ground state level. At 0 K, only the ground state is occupied.

Density of elementary excitations. There are no states within the energy gap  $\Delta$ .

Temperature dependence of  $\Delta$ :

$$\Delta(T) \approx \Delta(0 \text{ K}) \sqrt{\cos\left(\frac{\pi}{2} \left(\frac{T}{T_c}\right)^2\right)}$$

Original BCS theory has been derived using “mean field approximation” – valid for  $0 \leq T < T_c$ . Ginzburg-Landau theory is valid for  $T \approx T_c$ . Gor’kov showed that  $\lim_{T \rightarrow T_c} (\text{BCS}) = \text{GL}$ .

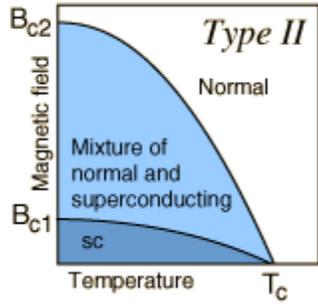

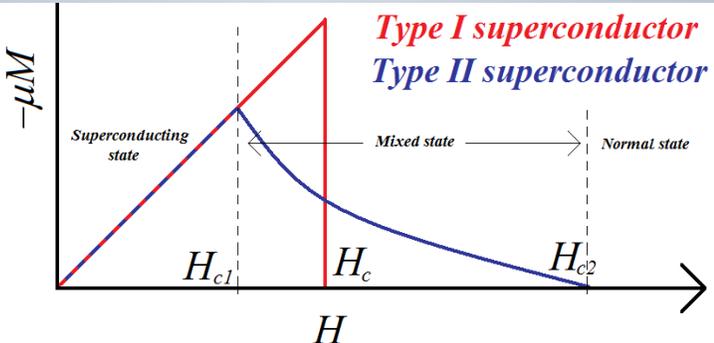

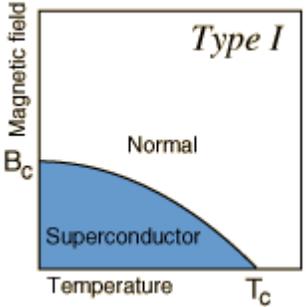

# Classification of superconductors

## Type-I superconductor:

- Meissner effect complete
- Sharp transition NC/SC at field  $H_c$
- $\kappa = \lambda_L/\xi < 1/\sqrt{2}$

## Type-II superconductor:

- Meissner effect incomplete
- Two critical fields  $H_{c1}$  and  $H_{c2}$
- $\kappa > 1/\sqrt{2}$

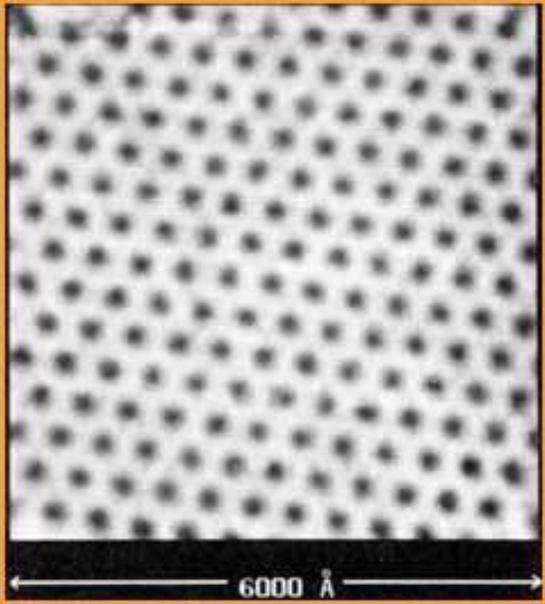

- Examples: Pb, Sn, Hg, Cr, Al

- Examples: Nb, alloys

# Flux quantization

- In Type-II superconductors flux tubes are created each carrying one flux quantum (the minimal flux allowed by quantum mechanics)
- Flux tubes are repulsive creating, therefore the vortex lattice

STM image of Vortex lattice, 1989  
H. F. Hess et al. Phys. Rev. Lett. 62, 214, 1989

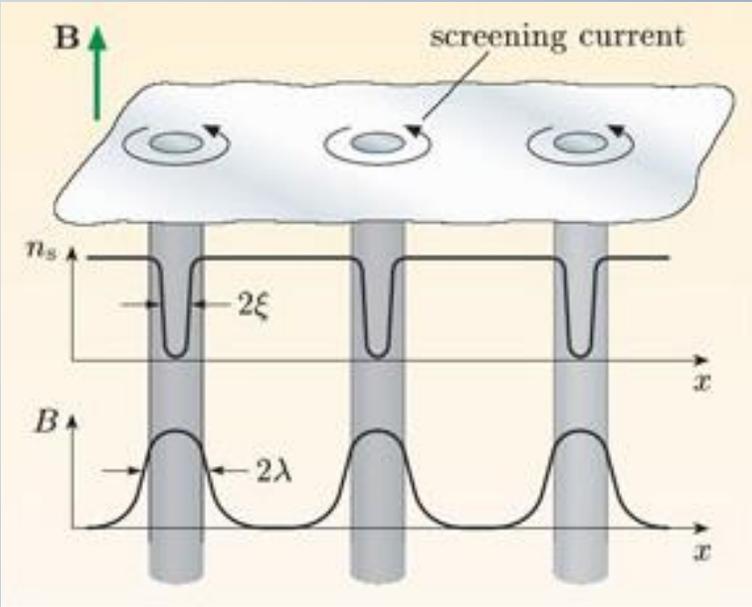

Photo:  
Reidar Hahn

# Field limits for type-II superconductors

- $H < H_{c1}$ : perfect Meissner state
- $H_{c1} < H < H_{c2}$ : penetration and oscillation of vortices give rise to strong dissipation – not useable for RF.

But ...

- The Meissner state can remain metastable for  $H_{c1} < H < H_{sh}$ , if vortices can be prevented from entering (Bean-Livingston barrier).

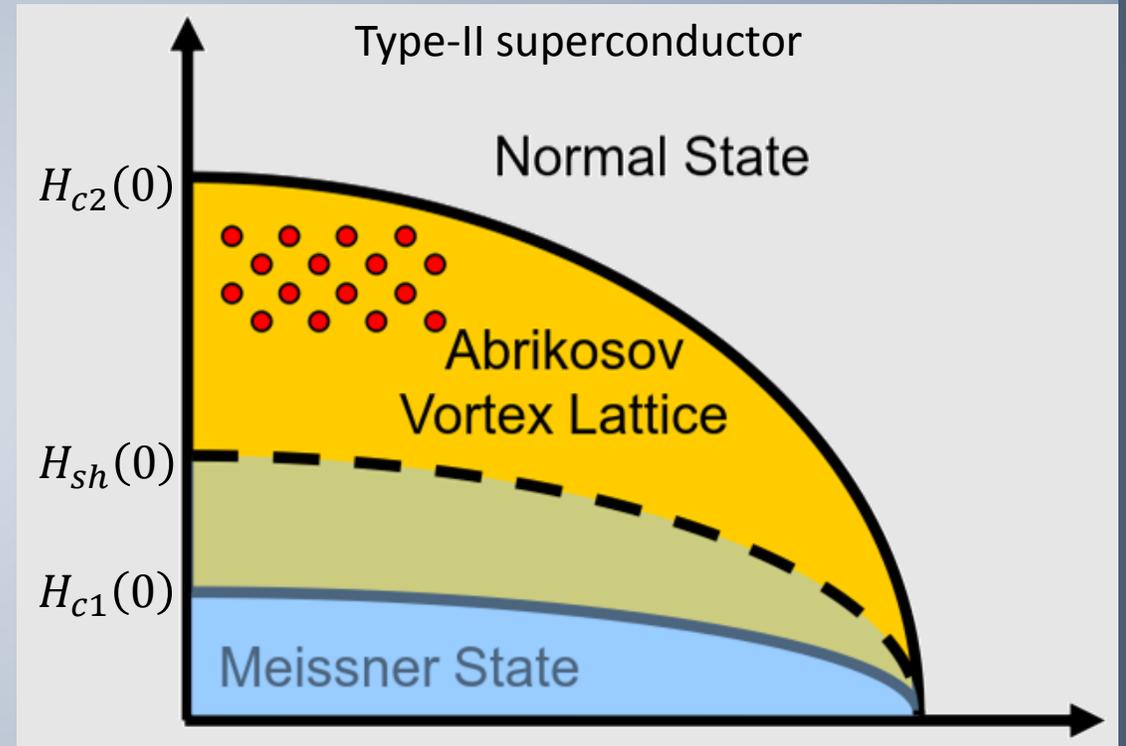

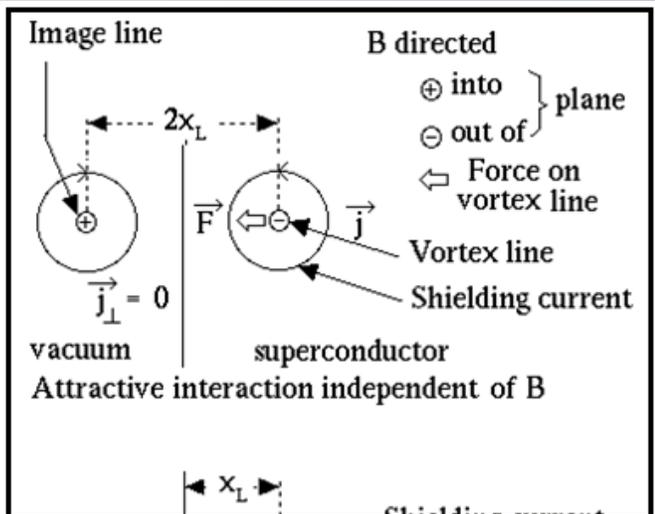

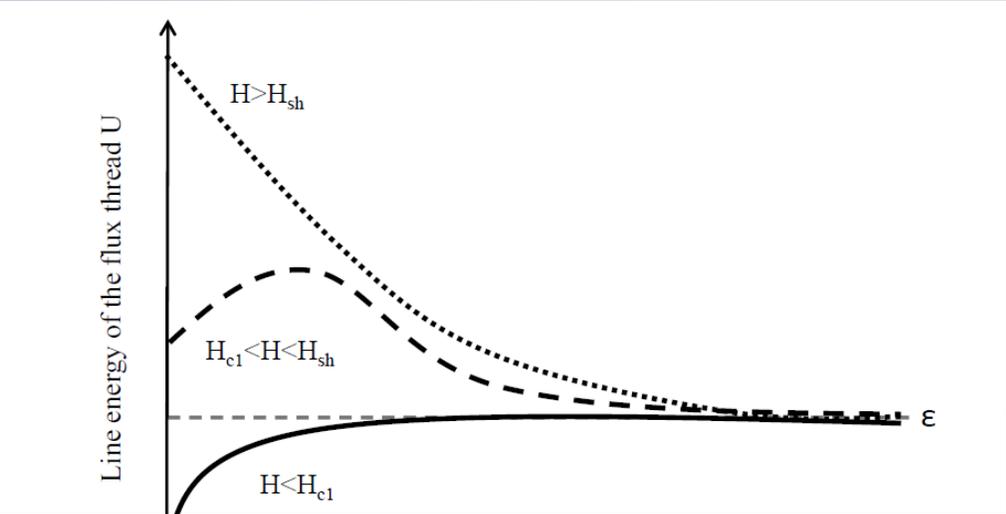

Photo: Reidar Hahn

# The superheating field

The superheating field  $H_{sh}$  is set by the competition between magnetic pressure (imposed by the external magnetic field), the energy cost to destroy superconductivity, and the attractive force due to the zero-current boundary condition at the interface.

- $H_{c1}$  is the field where it is energetically favourable for the flux to be in the superconductor.
- $H_{sh}$  is the field where the Bean-Livingston barrier for flux entry disappears
- Defects can serve as entry points for flux preventing superheating

## RF case

- The time-dependent magnetic field in the penetration depth  $\lambda_L$  will generate an electric field

$$\nabla \times \vec{E} = -\frac{\partial \vec{B}}{\partial t}.$$

- At  $T > 0$  K, there will exist a fraction of unpaired electrons:

$$n_n(T) \propto e^{-\frac{\Delta}{k_B T}}$$

- Since Cooper pairs have inertia, they cannot shield these NC electrons from  $E$ , hence

$$R_s > 0.$$

Photo:  
Reidar Hahn

# Two-fluid model

- Proposed by Gorter and Casimir already in 1943: Charge carriers are divided in two subsystems, superconducting carriers of density  $n_s$  and normal electrons of density  $n_n$ .
- Assume  $\frac{n_s}{n} = 1 - \left(\frac{T}{T_c}\right)^4$ ,  $\frac{n_n}{n} = \left(\frac{T}{T_c}\right)^4$ ,  $n_s + n_n = n$ .
- The total current results from  $J = J_s + J_n$

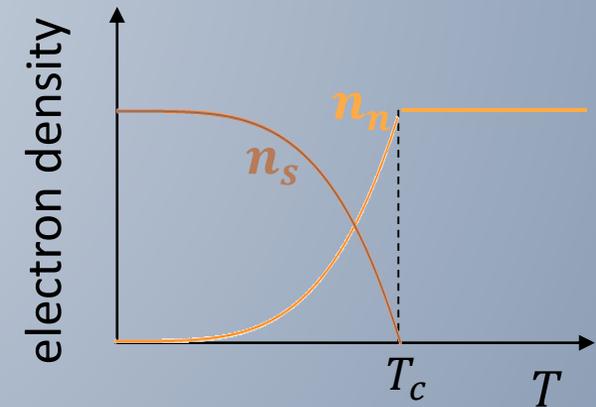

Photo:  
Reidar Hahn

## RF surface impedance of SC

- From 1<sup>st</sup> London equation:  $\frac{\partial \vec{J}_s}{\partial t} = \frac{\vec{E}}{\mu \lambda_L^2}$ ,  $\rightarrow J_s = -j \frac{1}{\omega \mu \lambda_L^2} E$ , or  $J_s = -j \frac{n_s e^2}{m \omega} E$ .

- For the unpaired electrons (Ohm's law):  $J_n = \frac{n_n e^2 \tau}{m} E$ .

- For the total current:

$$J = J_n + J_s = (\sigma_n - j\sigma_s)E = \left( \frac{n_n e^2 \tau}{m} - j \frac{n_s e^2}{m \omega} \right) E$$

- Surface impedance:

$$Z_s = R_s + jX_s = \sqrt{\frac{j\omega\mu}{\sigma_n - j\sigma_s}}$$

- With the 2-fluid model this results in:

$$R_s = \frac{1}{2} \mu \omega^2 \sigma_n \lambda_L^3$$
$$X_s = \omega \mu \lambda_L$$

Reidar Hahn

## RF surface resistance of a SC

We found  $R_S = \frac{1}{2} \mu \omega^2 \sigma_n \lambda_L^3$  – what does this mean?

- **Frequency dependence:**

$R_S \propto \omega^2$ : use low frequency cavities to reduce power dissipation!

- **Temperature dependence:**

from two-fluid model:  $\sigma_n \propto n_n \propto e^{-\frac{\Delta}{k_B T}}$

$$R_S \propto \exp\left(-\frac{\Delta}{k_B T}\right)$$

- There are “better” approximations around, most famous the formulae developed by Halbritter (1970), which approximate  $R_S$  as a function of  $\omega$ ,  $T$ ,  $\xi_0$ ,  $\lambda_L$ ,  $T_c$ ,  $\Delta$ , and  $\ell$ , see e.g. here:

# Halbritter approximation example

## SRIMP

This webpage calculates BCS surface resistance under wide range of conditions, and is based on a program by Jurgen Halbritter. [J. Halbritter, Zeitschrift für Physik 238 (1970) 466]

Enter material parameters below, and click submit to calculate the BCS surface resistance. Results are given in a new window.

**Please be aware that frequencies much lower than 1 MHz may cause substantial processing times (depending on the user's computer).**

Submit

Frequency (MHz):	<input type="text" value="1300"/>
Transition temperature (K):	<input type="text" value="9.2"/>
DELTA/kTc:	<input type="text" value="1.86"/>
London penetration depth (A):	<input type="text" value="330"/>
Coherence length (A):	<input type="text" value="400"/>
RRR:	<input type="text" value="300"/>
Accuracy of computation:	<input type="text" value=".001"/>
Temperature (of operation):	<input type="text" value="2"/>

## Results:

**Diffuse Reflection:** Resistance (Ohm):   
Penetration Depth (um): 0.037746828693838295

## Input Parameters:

Frequency (MHz): 1300  
Transition temperature (K): 9.2  
DELTA/kTc: 1.86  
London penetration depth (A): 330  
Coherence length (A): 400  
RRR: 300  
Accuracy of computation: 0.001  
Temperature (of operation): 2

Be careful here. The website suggests 40 nm. The input required is  $\pi\xi_0/2$ , while  $\xi_0 \approx 38$  nm for Nb.

Reidar Hahn

# $R_S$ dependence on material purity

• We had introduced above:

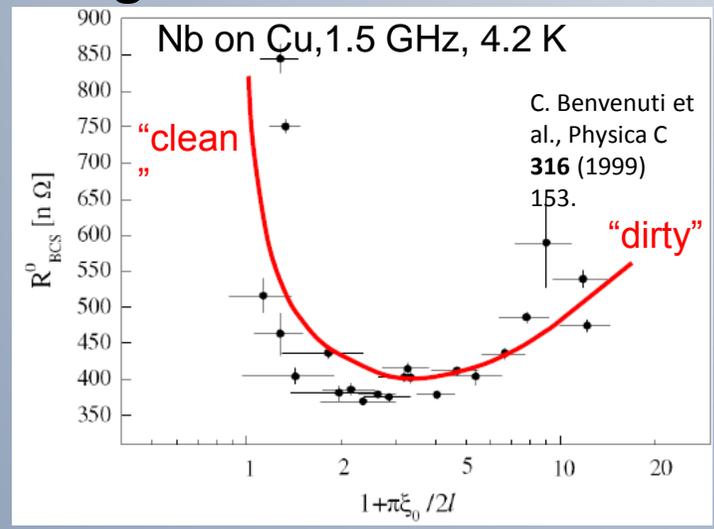

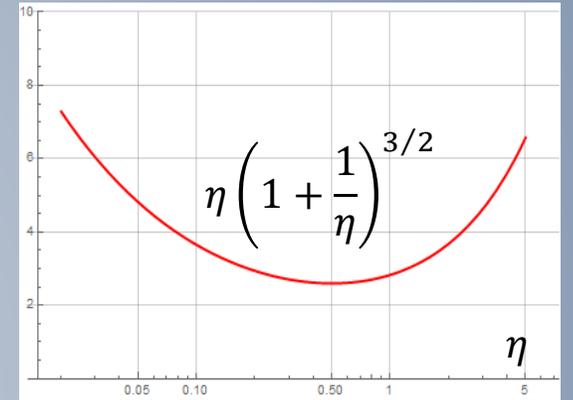

- $\lambda(\ell) = \lambda_L \sqrt{1 + \frac{\xi_0}{\ell}}$
- $\sigma_1 \propto \ell$

$$R_S \propto \left(1 + \frac{\xi_0}{\ell}\right)^{3/2} \frac{\ell}{\xi_0}$$

• It follows that  $R_S$  has a local minimum at  $\ell/\xi_0 = 1/2$ .

• This is remarkable: at some point, increasing  $\ell$  (cleaner material) makes things worse!

- This example: Nb films sputtered on Cu
- By changing the sputtering species, the mean free path was varied.
- RRR of niobium on copper cavities can be tuned for lowest  $R_S$ .

Reidar Hahn

# BCS resistance

$$\begin{aligned} \bullet R_{S,BCS} &\approx \frac{A}{2} \omega^2 \mu^2 \left( \lambda_L \sqrt{1 + \frac{\xi}{\ell}} \right)^3 \frac{RRR}{\rho_n(300 \text{ K})} e^{-\frac{\Delta}{k_B T_c} \frac{T_c}{T}} \\ &\approx 1.643 \cdot 10^{-5} \frac{T_c}{T} \left( \frac{f}{\text{GHz}} \right)^2 e^{-1.92 \frac{T_c}{T}} \end{aligned}$$

Reidar Hahn

# Residual resistance

- In real, technical superconductors, the observed surface resistance deviates from the BCS prediction and can be written as  $R_S = R_{BCS} + R_{res}$ .
- Possible contributions to  $R_{res}$ :
  - Trapped magnetic flux and thermal currents
  - Lossy oxides, metallic hydrides
  - Normal-conducting precipitates
  - Grain boundaries
  - Interface losses
  - Magnetic impurities
  - Subgap states

For Nb,  $R_{res} \approx (1 \dots 10)$  nΩ often dominates  $R_S$  at low  $f$  ( $< 1$  GHz) and low  $T$  ( $< 2$  K).
