

# Beam Instrumentation & Diagnostics Part 2

*CAS Introduction to Accelerator Physics*

Vysoké Tatry, 19<sup>th</sup> of September 2019

Peter Forck

Gesellschaft für Schwerionenforschung (GSI)

[p.forck@gsi.de](mailto:p.forck@gsi.de)

2<sup>nd</sup> part of this lecture covers:

- Transverse profile techniques
- Emittance determination at transfer lines
- Diagnostics for bunch shape determination

# Measurement of Beam Profile

The beam width can be changed by focusing via quadrupoles.

Transverse matching between ascending accelerators is done by focusing.

→ Profiles have to be controlled at many locations.

**Synchrotrons:** Lattice functions  $\beta(s)$  and  $D(s)$  are fixed  $\Rightarrow$  width  $\sigma$  and emittance  $\varepsilon$  are:

$$\sigma_x^2(s) = \varepsilon_x \beta_x(s) + \left( D(s) \frac{\Delta p}{p} \right)^2 \quad \text{and} \quad \sigma_y^2(s) = \varepsilon_y \beta_y(s) \quad (\text{no vertical bend})$$

**Transfer lines:** Lattice functions are 'smoothly' defined due to variable input emittance.

**Typical beam sizes:**

**e<sup>-</sup>-beam:** typically  $\varnothing$  0.01 to 3 mm, **protons:** typically  $\varnothing$  1 to 30 mm

**A great variety of devices are used:**

- **Optical techniques:** Scintillating screens (all beams),  
synchrotron light monitors (e<sup>-</sup>), optical transition radiation (e<sup>-</sup>, high energetic p),  
ionization profile monitors (protons)
- **Electronics techniques:** Secondary electron emission SEM grids, wire scanners (all)

# Scintillation Screen

**Scintillation:** Particle's energy loss in matter causes emission of light

→ the most direct way of profile observation as used from the early days on!

# Example of Screen based Beam Profile Measurement

**Example:** GSI LINAC, 4 MeV/u, low current, YAG:Ce screen

## Advantage of screens:

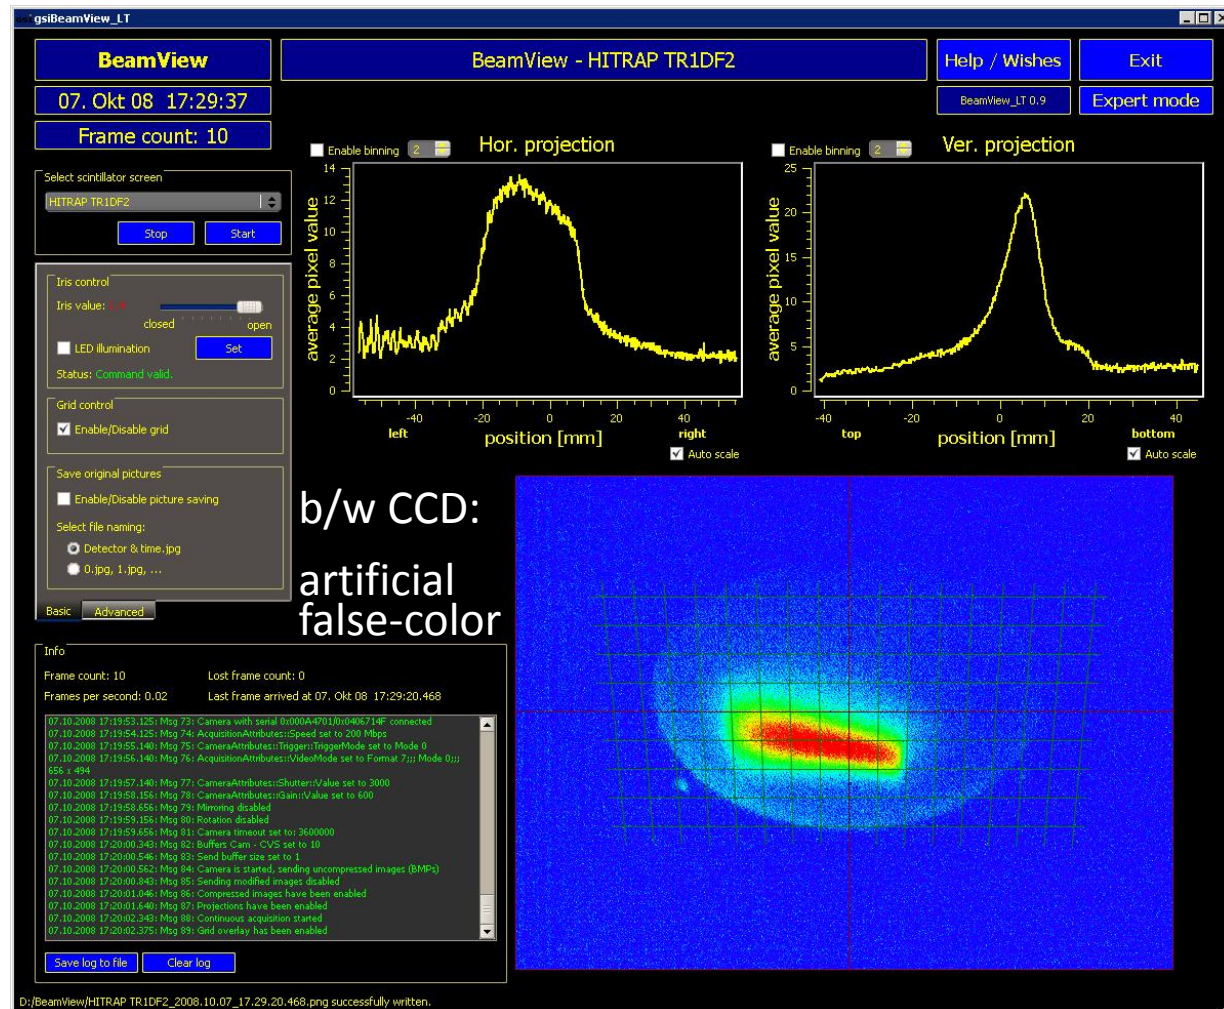

- Direct 2-dim measurement
  - High spatial resolution
  - Cheap realization
- ⇒ widely used at transfer lines

## Disadvantage of screens:

- Intercepting device
- Some material might brittle
- Low dynamic range
- Might be destroyed by the beam

Observation with  
a CCD, CMOS or video camera

## Scintillation Screen (beam stopped)

# Light output from various Scintillating Screens

*Example: Color CCD camera: Images at different particle intensities determined for U at 300 MeV/u*

**Alumina:  $\text{Al}_2\text{O}_3$**

**CsI:Tl**

**Chromox:  $\text{Al}_2\text{O}_3$ :Cr**

**P43**

**YAG:Ce**

**Quartz**

**Quartz:Ce**

**$\text{ZrO}_2$ :Mg**

- Very different light yield i.e. photons per ion's energy loss
- Different wavelength of emitted light

## *Some materials and their basic properties:*

Name	Type	Material	Activ.	Max. $\lambda$	Decay
Chromox	Cera- mics	$\text{Al}_2\text{O}_3$	Cr	700 nm	$\approx 10$ ms
Alumina		$\text{Al}_2\text{O}_3$	Non	380 nm	$\approx 10$ ns
YAG:Ce	Crystal	$\text{Y}_3\text{Al}_5\text{O}_{12}$	Ce	550 nm	200 ns
P43	Powder	$\text{Gd}_2\text{O}_3\text{S}$	Tb	545 nm	1 ms
P46		$\text{Y}_3\text{Al}_5\text{O}_{12}$	Ce	530 nm	300 ns
P47		$\text{Y}_3\text{Si}_5\text{O}_{12}$	Ce&Tb	400 nm	100 ns

## Properties of a good scintillator:

- Large light output at optical wavelength  
→ standard CCD camera can be used
- Large dynamic range → usable for different currents
- Short decay time → observation of variations
- Radiation hardness → long lifetime
- Good mechanical properties → typ. size up to  $\varnothing$  10 cm  
(Phosphor Pxx grains of  $\varnothing \approx 10$   $\mu\text{m}$  on glass or metal).

Standard drive with P43 screen

## Outline:

- Scintillation screens:
  - emission of light, universal usage, limited dynamic range
- **SEM-Grid:** emission of electrons, workhorse, limited resolution
- **Wire scanner**
- **Ionization Profile Monitor**
- **Optical Transition Radiation**
- **Synchrotron Light Monitors**
- **Summary**

# Secondary Electron Emission by Ion Impact

## Energy loss of ions in metals close to a surface:

Closed collision with large energy transfer:  $\rightarrow$  fast  $e^-$  with  $E_{kin} \gg 100$  eV

Distant collision with low energy transfer:  $\rightarrow$  slow  $e^-$  with  $E_{kin} \leq 10$  eV

$\rightarrow$  'diffusion' & scattering with other  $e^-$ : scattering length  $L_s \approx 1 - 10$  nm

$\rightarrow$  at surface  $\approx 90\%$  probability for escape

Secondary **electron yield** and energy distribution comparable for all metals!

$$\Rightarrow Y = \text{const.} * dE/dx \quad (\text{Sternglass formula})$$

From E.J. Sternglass, Phys. Rev. 108, 1 (1957)

# Secondary Electron Emission Grids = SEM-Grid

**Beam surface interaction:**  $e^-$  emission  $\rightarrow$  measurement of current.

*Example: 15 wire spaced by 1.5 mm:*

*SEM-Grid feed-through on CF200:*

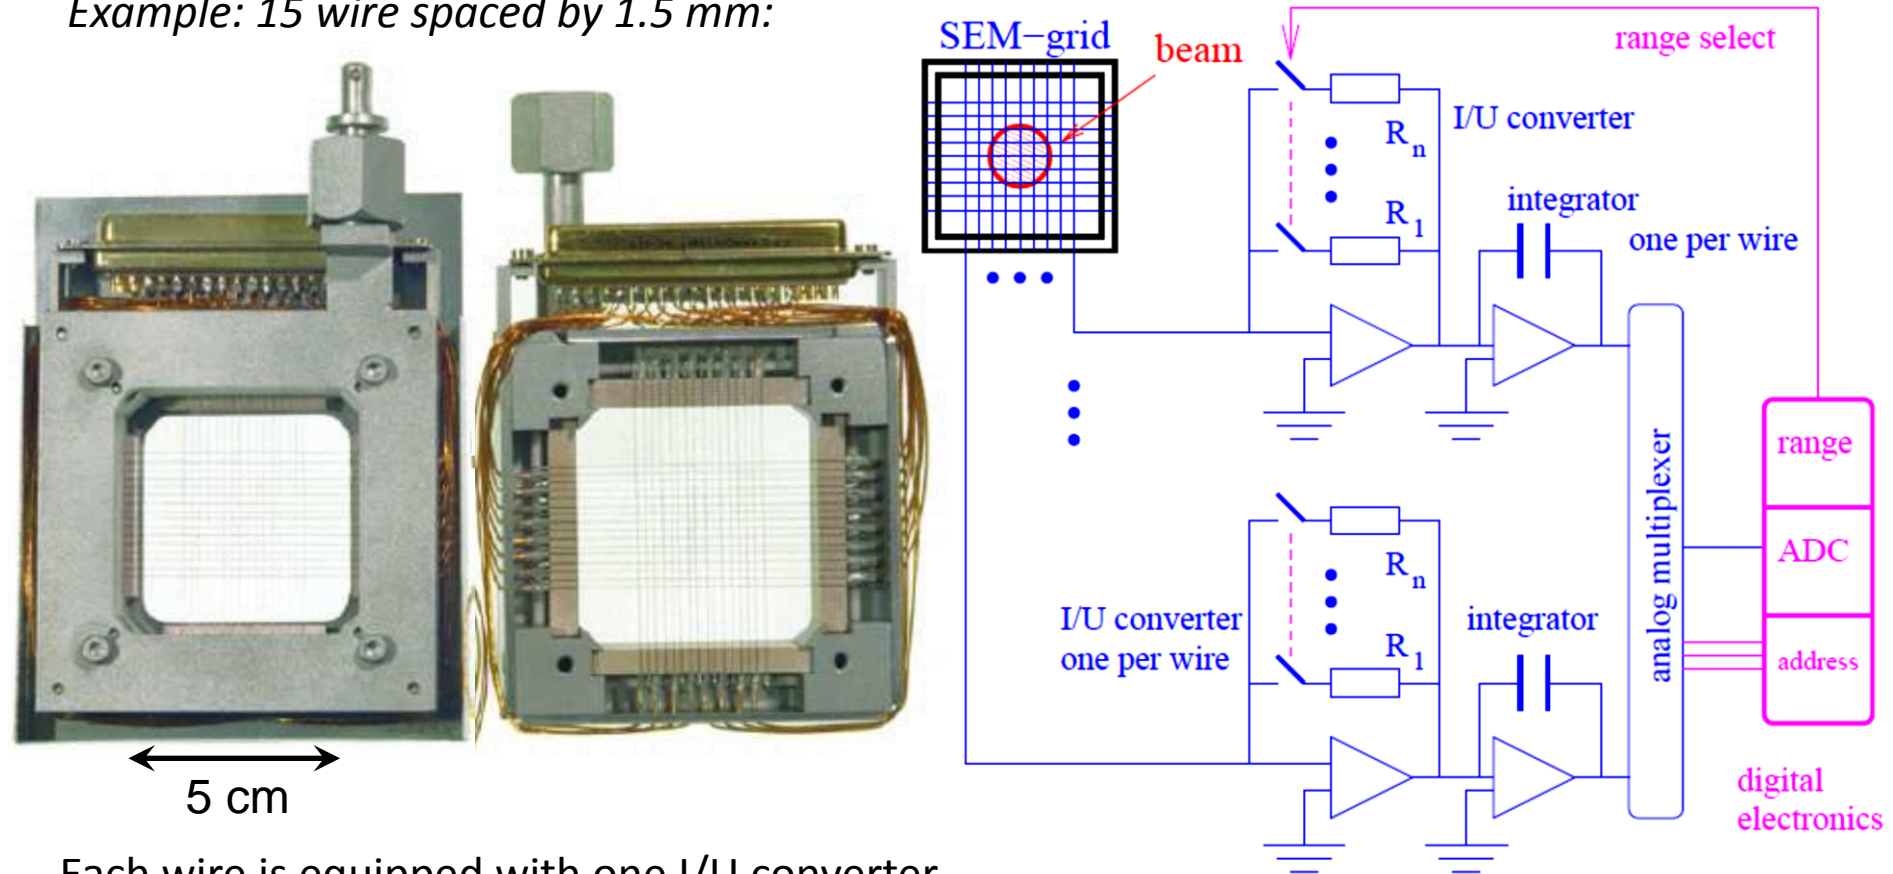

Parameter	Typ. value
# wires per plane	10 ...100
Active area	$(5...20 \text{ cm})^2$
Wire $\varnothing$	25....100 $\mu\text{m}$
Spacing	0.3...2 mm
Material	e.g. W or Carbon
Max. beam power	1 W/mm

# Secondary Electron Emission Grids = SEM-Grid

**Beam surface interaction:**  $e^-$  emission  $\rightarrow$  measurement of current.

*Example: 15 wire spaced by 1.5 mm:*

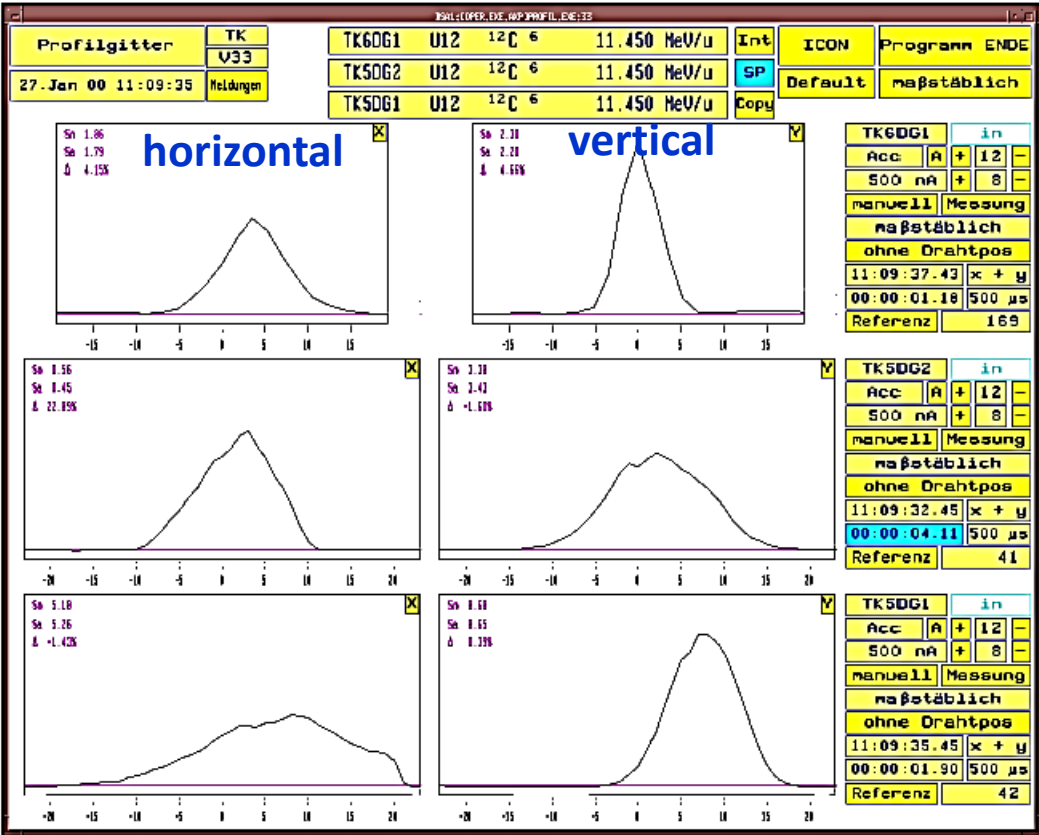

Each wire is equipped with one I/U converter  
different ranges settings by  $R_i$   
 $\rightarrow$  very large dynamic range up to  $10^6$ .

# Example of Profile Measurement with SEM-Grids

Even for low energies, several SEM-Grid can be used due to the  $\approx 80\%$  transmission  
 $\Rightarrow$  frequently used instrument beam optimization: setting of quadrupoles, energy....

Example:  $C^{6+}$  beam of 11.4 MeV/u at different locations at GSI-LINAC

beam 

## Outline:

- Scintillation screens:
  - emission of light, universal usage, limited dynamic range
- SEM-Grid: emission of electrons, workhorse, limited resolution
- **Wire scanner:** emission of electrons, workhorse, scanning method
- **Ionization Profile Monitor**
- **Optical Transition Radiation**
- **Synchrotron Light Monitors**
- **Summary**

# Slow, linear Wire Scanner

**Idea: One wire is scanned through the beam!**

Wire diameter  $100\ \mu\text{m} < d_{\text{wire}} < 10\ \mu\text{m}$

**Slow, linear scanner are used for:**

- Low energy protons
- High resolution measurements for  $e^-$  beam  
by de-convolution  $\sigma_{\text{beam}}^2 = \sigma_{\text{meas}}^2 - d_{\text{wire}}^2$   
 $\Rightarrow$  resolution down to  $1\ \mu\text{m}$  range can be reached
- Detection of beam halo

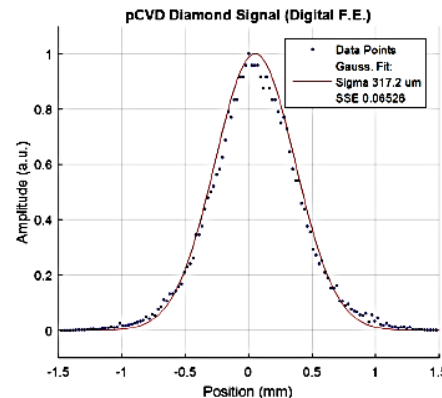

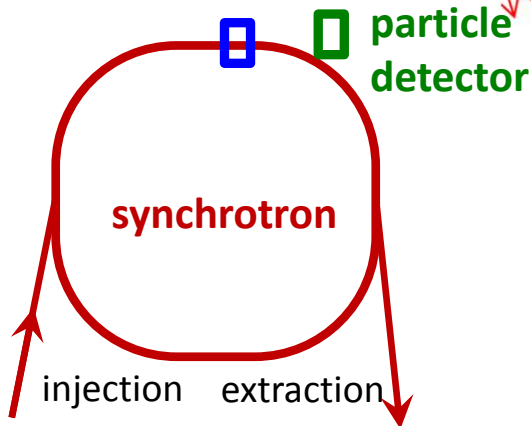

# The Artist view of a Beam Scraper or Scanner

# Fast, Flying Wire Scanner

In a synchrotron one wire is scanned though the beam as fast as possible.

Fast pendulum scanner for synchrotrons; sometimes it is called '*flying wire*':

From <https://twiki.cern.ch/twiki/bin/viewauth/BWSUpgrade/>

# Usage of Flying Wire Scanners

**Material:** carbon or SiC → low Z-material for low energy loss and high temperature.

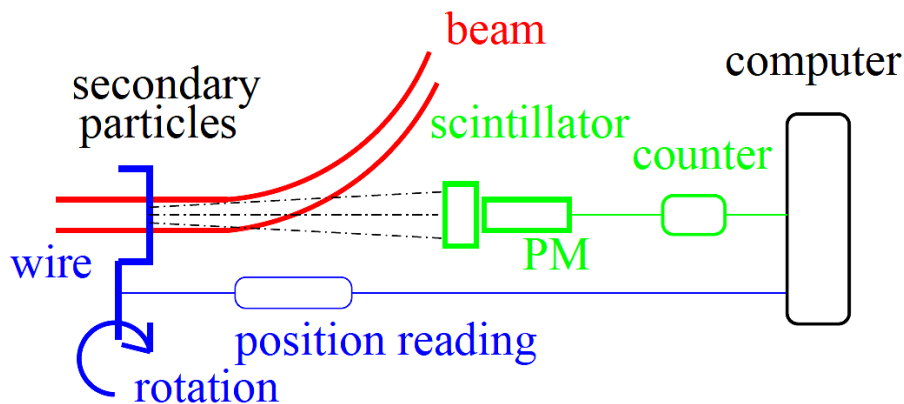

**Thickness:** down to 10 μm → high resolution.

**Detection:** High energy **secondary particles** with a detector like a beam loss monitor

## Secondary particles:

**Proton beam** → hadrons shower ( $\pi$ , n, p...)

**Electron beam** → Bremsstrahlung photons.

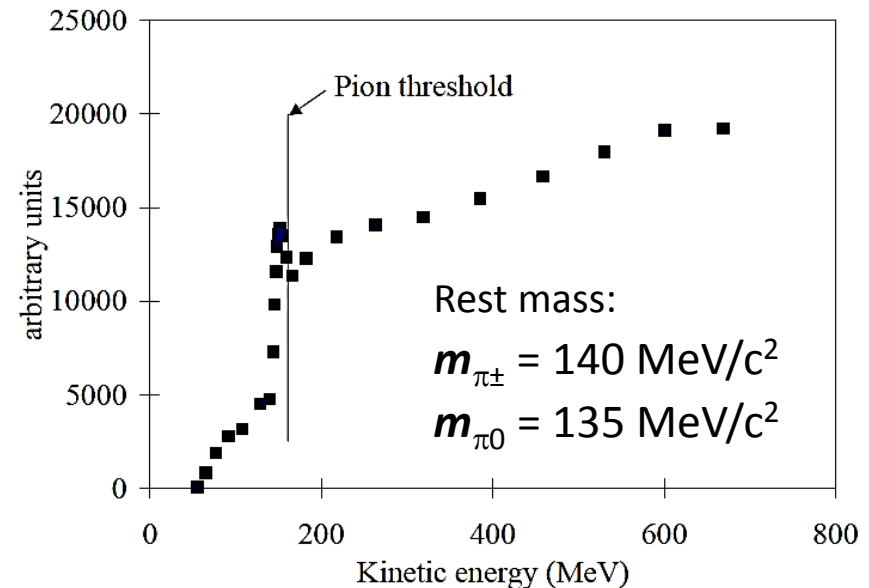

## Kinematics of flying wire:

Velocity during passage typically 10 m/s = 36 km/h and

typical beam size  $\varnothing$  10 mm  $\Rightarrow$  time for traversing the beam  $t \approx 1$  ms

**Challenges:** Wire stability for fast movement with high acceleration

## Proton impact on scanner at CERN-PS Booster:

U. Raich et al., DIPAC 2005

# The Artist View of a Wire Scanner

**Purpose:** The Faraday Cup Award, donated by Bergov Instrumentation of Saint Genis, France, is intended to recognize and encourage innovative achievements in the field of accelerator beam instrumentation.

**Award:** The award consists of a \$5000 prize and a certificate to be presented at the next US Beam Instrumentation Workshop which will be held at Fermi National Laboratory on May 1-4, 2006. Winners participating in the BIW will share a \$1,000 travel allowance. The selection of recipients is the responsibility of the BIW Organizing Committee.

**Criteria:** The Faraday Cup Award shall be presented for outstanding contribution to the development of an innovative beam diagnostics instrument of proven workability. The prize is only awarded for demonstrated device performance and published contribution.

**Criteria Interpretation:** Beam Diagnostic Instrument: A device to measure the properties of charged elementary particle, atomic or simple molecular beams during or after acceleration, or the properties of neutral particle beams produced in an intermediate state of charged particle acceleration. The device may operate by detecting secondary beams of charged, neutral, massive or massless particles. But its purpose should be to diagnose the primary charged particle beam. The mass of primary beam particles shall be no greater than the order of 10.0 atomic mass units.

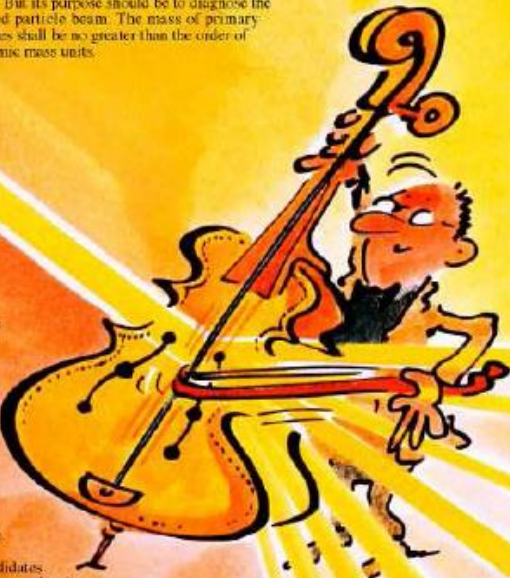

**Delivered performance:** The performance of the device should have been evaluated using a charged particle beam, rather than in a "bench top" demonstration. Publication: A description of the device, its operating principle, and its performance should have been published in a journal or in the proceedings of a conference or workshop that is in the public domain. Laboratory design notes, internal technical notes, etc. do not qualify but may be submitted to support other publications. Full and open disclosure is necessary to the extent that a potential user could design a similar device. More than one article may be submitted (together) to satisfy this requirement; for example, an article describing the principle plus another article describing the performance.

**Eligibility:** Nominations are open to candidates of any nationality for work done at any geographical location. There are no restrictions for candidates; however, in the event of deciding between works of similar quality, preference will be given to candidates in an early stage of their beam instrumentation career. The award may be shared between persons contributing to the same accomplishment. Once accepted by the Award Committee a nomination shall remain eligible for three successive competitions unless withdrawn by a candidate.

**Disclosure:** The Award Committee may release the names of entrants and a list of publications related to an entry if requested by a third party. Unpublished supporting material will not be disclosed nor will the names of persons supporting a nomination. Discussion regarding individual entries, scoring, etc. is regarded as confidential and will not be disclosed.

**Nominations:** The nomination package shall include the name of the candidate, relevant publications, a statement outlining his/her personal contribution and that of others, letters from two professional accelerator physicists, engineers or laboratory administrative personnel who are familiar with the device and its development. Two master copies of this package, suitable for copying, must be submitted not later than Oct. 14, 2005 to:

Fermilab MS 308, P. O. Box 500 Batavia, IL 60510, U.S.A.

# Comparison between SEM-Grid and slow Wire Scanners

**Grid:** Measurement at a single moment in time

**Scanner:** Fast variations can not be monitored

→ for pulsed LINACs precise synchronization is needed

---

**Grid:** Not adequate at synchrotrons for stored beam parameters

**Scanner:** At high energy synchrotrons flying wire scanners are nearly non-destructive

---

**Grid:** Resolution of a grid is fixed by the wire distance (typically 1 mm)

**Scanner:** For slow scanners the resolution is about the wire thickness (down to 10  $\mu\text{m}$ )

→ used for e<sup>-</sup>-beams having small sizes (down to 10  $\mu\text{m}$ )

---

**Grid:** Needs one electronics channel per wire

→ expensive electronics and data acquisition

**Scanner:** Needs a precise movable feed-through → expensive mechanics.

## Outline:

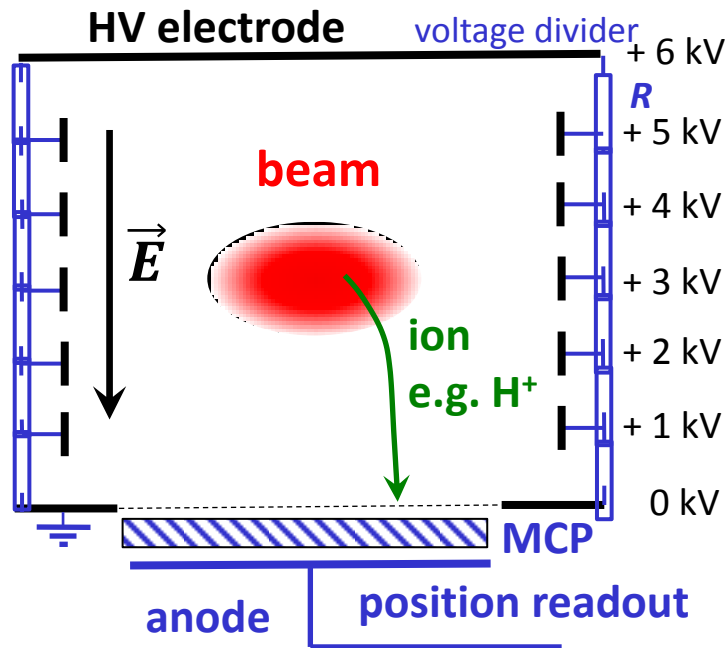

- Scintillation screens:
  - emission of light, universal usage, limited dynamic range
- SEM-Grid: emission of electrons, workhorse, limited resolution
- Wire scanner: emission of electrons, workhorse, scanning method
- **Ionization Profile Monitor:**
  - secondary particle detection from interaction beam-residual gas
- **Optical Transition Radiation**
- **Synchrotron Light Monitors**
- **Summary**

# Ionization Profile Monitor at GSI Synchrotron

**Non-destructive** device for proton synchrotron:

- beam ionizes the residual gas by electronic stopping
- gas ions or  $e^-$  accelerated by  $E$ -field  $\approx 1$  kV/cm
- spatial resolved single particle detection

**Typical** vacuum pressure:

Transfer line:  $N_2$   $10^{-8} \dots 10^{-6}$  mbar  $\cong 3 \cdot 10^8 \dots 3 \cdot 10^{10} \text{ cm}^{-3}$   
 Synchrotron:  $H_2$   $10^{-11} \dots 10^{-9}$  mbar  $\cong 3 \cdot 10^5 \dots 3 \cdot 10^7 \text{ cm}^{-3}$

*Realization at GSI synchrotron:  
One monitor per plane*

# Ionization Profile Monitor Realization

The realization for the heavy ion storage ring ESR at GSI: *Realization at GSI synchrotron:

# 'Adiabatic' Damping during Acceleration

The emittance  $\varepsilon = \int dx dx'$  is defined via the position deviation and angle in **lab-frame**

After acceleration the longitudinal velocity is increased  $\Rightarrow$  angle  $\phi$  is smaller

The angle is expressed in momenta:  $x' = p_{\perp} / p_{\parallel}$  the emittance is  $\langle xx' \rangle = 0$ :  $\varepsilon = x \cdot x' = x \cdot p_{\perp} / p_{\parallel}$

$\Rightarrow$  under ideal conditions the emittance can be normalized to the momentum  $p_{\parallel} = \gamma \cdot m \cdot \beta c$

$\Rightarrow$  normalized emittance  $\varepsilon_{norm} = \beta \gamma \cdot \varepsilon$  is preserved with the Lorentz factor  $\gamma$  and velocity  $\beta = v/c$

**Example:** Acceleration in GSI-synchrotron for  $C^{6+}$  from 6.7  $\rightarrow$  600 MeV/u ( $\beta = 12 \rightarrow 79\%$ ) observed by IPM

$$\text{theoretical width: } \langle x \rangle_f = \sqrt{\frac{\beta_i \cdot \gamma_i}{\beta_f \cdot \gamma_f}} \cdot \langle x \rangle_i$$

$$= 0.33 \cdot \langle x \rangle_i$$

$$\text{measured width: } \langle x \rangle_f \approx 0.37 \cdot \langle x \rangle_i$$

IPM is well suited

for long time observations

without beam disturbance

$\rightarrow$  mainly used at proton synchrotrons.

## Outline:

- Scintillation screens:
  - emission of light. universal usage, limited dynamic range
- SEM-Grid: emission of electrons, workhorse, limited resolution
- Wire scanner: emission of electrons, workhorse, scanning method
- Ionization Profile Monitor:
  - secondary particle detection from interaction beam-residual gas
- **Optical Transition Radiation:**
  - crossing material boundary, for relativistic beams only
- **Synchrotron Light Monitors**
- **Summary**

# Optical Transition Radiation: Depictive Description

## Optical Transition Radiation OTR for a single charge $e$ :

Assuming a charge  $e$  approaches an ideal conducting boundary e.g. metal foil

- image charge is created by electric field
- dipole type field pattern
- field distribution depends on velocity  $\beta$  and Lorentz factor  $\gamma$  due to relativistic trans. field increase
- penetration of charge through surface within  $t < 10$  fs: sudden change of source distribution
- emission of radiation with dipole characteristic

Other physical interpretation: Impedance mismatch at boundary leads to radiation

# Optical Transition Radiation: Depictive Description

Optical Transition Radiation OTR can be described in classical physics:

approximated formula  
for normal incidence  
& in-plane polarization:

$$\frac{d^2W}{d\theta d\omega} \approx \frac{2e^2\beta^2}{\pi c} \cdot \frac{\sin^2\theta \cdot \cos^2\theta}{(1 - \beta^2 \cos^2\theta)^2}$$

$W$ : radiated energy

$\omega$ : frequency of wave

Angular distribution of radiation in optical spectrum:

- lobe emission pattern depends on velocity or Lorentz factor  $\gamma$
  - peak at angle  $\theta \approx 1/\gamma$
  - emitted energy i.e. amount of photons scales with  $W \propto \beta^2$
  - broad wave length spectrum (i.e. no dependence on  $\omega$ )
- suited for high energy electrons

sudden change charge distribution  
rearrangement of sources  $\Leftrightarrow$  radiation

**OTR is emitted by charged particle passage through a material boundary.**

Photon distribution:

within a solid angle  $d\Omega$  and  
Wavelength interval  $\lambda_{begin}$  to  $\lambda_{end}$

$$\frac{dN_{photon}}{d\Omega} = N_{beam} \cdot \frac{2e^2 \beta^2}{\pi c} \cdot \log\left(\frac{\lambda_{begin}}{\lambda_{end}}\right) \cdot \frac{\theta^2}{(\gamma^{-2} + \theta^2)^2}$$

- Detection: Optical  $400 \text{ nm} < \lambda < 800 \text{ nm}$   
using image intensified CCD
- Larger signal for relativistic beam  $\gamma \gg 1$
- Low divergence for  $\gamma \gg 1 \Rightarrow$  large signal
- $\Rightarrow$  **well suited for  $e^-$  beams**
- $\Rightarrow$  **p-beam only for  $E_{kin} > 10 \text{ GeV} \Leftrightarrow \gamma > 10$**

- Insertion of thin Al-foil under  $45^\circ$
- Observation of low light by CCD.

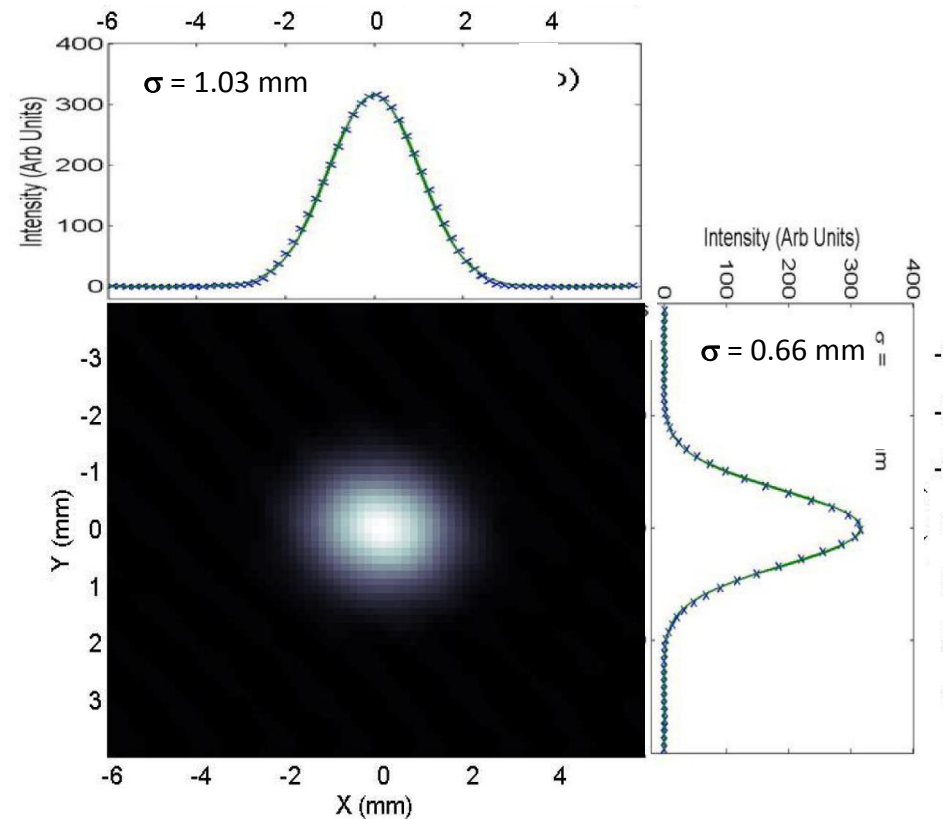

# OTR-Monitor: Technical Realization and Results

## Example of realization at TERATRON:

- Insertion of foil  
e.g. 5  $\mu\text{m}$  Kapton coated with 0.1  $\mu\text{m}$  Al
- Advantage:** thin foil  $\Rightarrow$  low heating & straggling  
2-dim image visible

Results at FNAL-TEVATRON synchrotron  
with 150 GeV proton  
Using fast camera: Turn-by-turn measurement

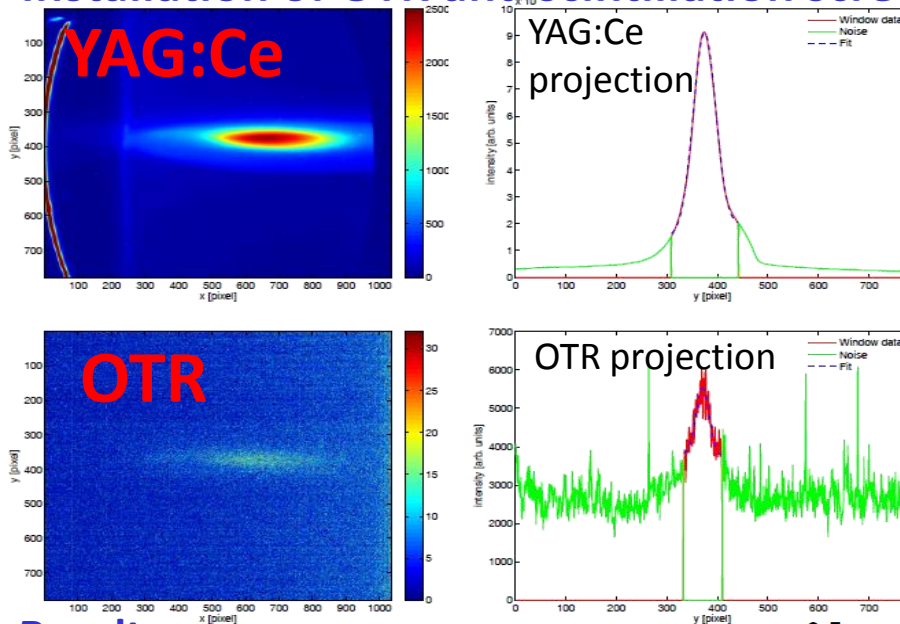

Courtesy V.E. Scarpine (FNAL) et al., BIW'06

# Optical Transition Radiation compared to Scintillation Screen

## Installation of OTR and scintillation screens on same drive:

Example: ALBA LINAC 100 MeV

## Results:

- Much more light from YAG:Ce for 100 MeV ( $\gamma=200$ ) electrons light output  $I_{YAG} \approx 10^5 I_{OTR}$
- Broader image from YAG:Ce due to finite YAG:Ce thickness

Courtesy of U. Iriso et al., DIPAC'09

# Comparison between Scintillation Screens and OTR

**OTR:** electrodynamic process → beam intensity linear to # photons, high radiation hardness

**Scint. Screen:** complex atomic process → saturation possible, for some low radiation hardness

---

**OTR:** thin foil Al or Al on Mylar, down to 0.25  $\mu\text{m}$  thickness

→ minimization of beam scattering (Al is low Z-material e.g. plastics like Mylar)

**Scint. Screen:** thickness  $\approx 1$  mm inorganic, fragile material, not always radiation hard

---

**OTR:** low number of photons → expensive image intensified CCD

**Scint. Screen:** large number of photons → simple CCD sufficient

---

**OTR:** complex angular photon distribution → resolution limited

**Scint. Screen:** isotropic photon distribution → simple interpretation

---

**OTR:** large  $\gamma$  needed →  $e^-$ -beam with  $E_{kin} > 100$  MeV, proton-beam with  $E_{kin} > 100$  GeV

**Scint. Screen:** for all beams

**Remark:** OTR **not** suited for LINAC-FEL due to **coherent** light emission (not covered here)  
but scintillation screens can be used.

## Outline:

- Scintillation screens:
  - emission of light, universal usage, limited dynamic range
- SEM-Grid: emission of electrons, workhorse, limited resolution
- Wire scanner: emission of electrons, workhorse, scanning method
- Ionization Profile Monitor:
  - secondary particle detection from interaction beam-residual gas
- Optical Transition Radiation:
  - crossing optical boundary, for relativistic beams only
- **Synchrotron Light Monitors**
  - photon detection of emitted synchrotron light in optical and X-ray range**
- **Summary**

# Synchrotron Light Monitor

An electron bent (i.e. accelerated) by a dipole magnet emit synchrotron light

see lecture of Lenny Rivkin

This light is emitted  
 into a cone of  
 opening  $2/\gamma$  in lab-frame.

⇒ Well suited for rel.  $e^-$

For protons:

Only for energies  $E_{kin} > 100$  GeV

The light is focused to a  
 intensified CCD.

**Advantage:**

Signal anyhow available!

**Rest frame of electron:**

**Laboratory frame:**

cone of synch. radiation

e-beam

angle  $\alpha$

dipole magnet  
 bending radius  $\rho$

lens filter

intensified  
 CCD camera

# Realization of a Synchrotron Light Monitor

Extracting out of the beam's plane by a (cooled) mirror

→ Focus to a slit + wavelength filter for optical wavelength

→ Image intensified CCD camera

**Example:** ESRF monitor from dipole with bending radius 22 m (blue or near UV)

Courtesy K. Scheidt et al., DIPAC 2005

# Result from a Synchrotron Light Monitor

**Example:** Synchrotron radiation facility APS accumulator ring and blue wavelength:

B.X. Yang (ANL) et al. PAC'97

**Advantage:** Direct measurement of 2-dim distribution, good optics for visible light

**Realization:** Optics outside of vacuum pipe

**Disadvantage:** Resolution limited by the diffraction due to finite apertures in the optics.

# 'Adiabatic Damping' for an Electron Beam

Example: Booster at the light source ALBA acceleration from 0.1 → 3 GeV within 130 ms

Profile measure by synchrotron light monitor:

Courtesy U. Iriso & M. Pont  
(ALBA) et al. IPAC 2011

The beam emittance is influenced by:

- Adiabatic damping
- Longitudinal momentum contribution

via dispersion  $\Delta x_D(s) = D(s) \cdot \frac{\Delta p}{p}$

total width  $\Delta x_{tot}(s) = \sqrt{\varepsilon\beta(s) + D(s) \cdot \frac{\Delta p}{p}}$

- Quantum fluctuation due to light emission

# The Artist View of a Synchrotron Light Monitor

# Diffraction Limit of Synchrotron Light Monitor

## Limitations:

Diffraction limits the resolution due to Fraunhofer diffraction

$$\Rightarrow \sigma \cong 0.6 \cdot (\lambda^2 / \rho)^{1/3}$$

$\approx 100 \text{ } \mu\text{m}$  for typical case

## Improvements:

### ➤ Shorter wavelength:

Using X-rays and an aperture of  $\varnothing 1\text{mm}$   
 → 'X-ray pin hole camera',  
 achievable resolution  $\sigma \approx 10 \text{ } \mu\text{m}$

### ➤ Interference technique:

At optical wavelength  
 using a double slit  
 → interference fringes  
 achievable resolution  $\sigma \approx 1 \text{ } \mu\text{m}$ .

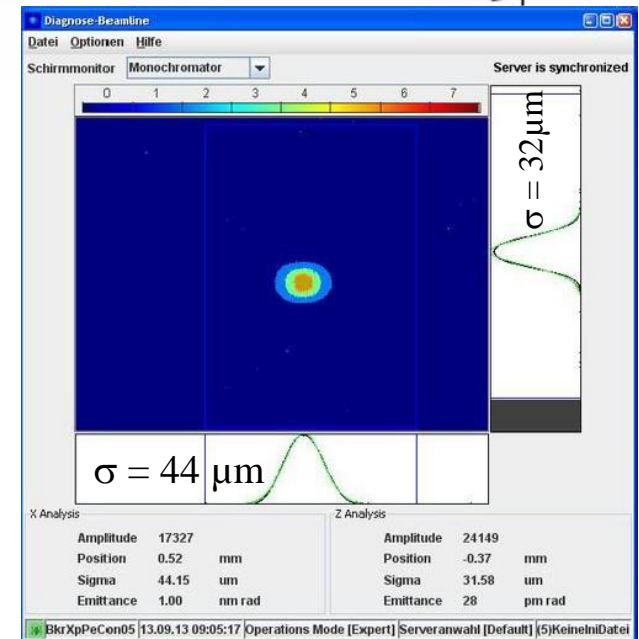

# X-ray Pin-Hole Camera

The diffraction limit is  $\Rightarrow \sigma \cong 0.6 \cdot (\lambda^2 / \rho)^{1/3} \Rightarrow$  *shorter wavelength by X-rays.*

Example: PETRA III result:

# Double Slit Interference for Radiation Monitors

The **blurring of interference pattern** due to finite size of the sources

⇒ spatial coherence parameter  $\gamma$  delivers **rms** beam size

i.e. ‘de-convolution’ of blurred image!

→ highest resolution, but complex method

## Typical resolution for three methods:

- Direct optical observation:  $\sigma \approx 100 \mu\text{m}$
- Direct x-ray observation :  $\sigma \approx 10 \mu\text{m}$
- Interference optical obser:  $\sigma \approx 1 \mu\text{m}$

SR source  
of finite width

Courtesy of V. Schlott PSI

Ideal double slit interference pattern:

Blurring by finite source size:

*Different techniques are suited for different beam parameters:*

**e<sup>-</sup>-beam:** typically  $\varnothing$  0.01 to 3 mm, **protons:** typically  $\varnothing$  1 to 30 mm

Intercepting  $\leftrightarrow$  non-intercepting methods

*Direct observation of electrodynamics processes:*

- Optical synchrotron radiation monitor: non-destructive, for e<sup>-</sup>-beams, complex, limited res.
- X-ray synchrotron radiation monitor: non-destructive, for e<sup>-</sup>-beams, very complex
- OTR screen: nearly non-destructive, large relativistic  $\gamma$  needed, e<sup>-</sup>-beams mainly

*Detection of secondary photons, electrons or ions:*

- Scintillation screen: destructive, large signal, simple setup, all beams
- Ionization profile monitor: non-destructive, expensive, limited resolution, for protons

*Wire based electronic methods:*

- SEM-grid: partly destructive, large signal and dynamic range, limited resolution
- Wire scanner: partly destructive, large signal and dynamics, high resolution, slow scan.

# Measurement of transverse Emittance

The emittance characterizes the whole beam quality, assuming linear behavior as described by second order differential equation.

It is defined within the phase space as:  $\varepsilon_x = \frac{1}{\pi} \int_A dx dx'$

The measurement is based on determination of:

**Either** profile width  $\sigma_x$  and angular width  $\sigma_x'$  at one location

**Or** profile width  $\sigma_x$  at different locations and linear transformations.

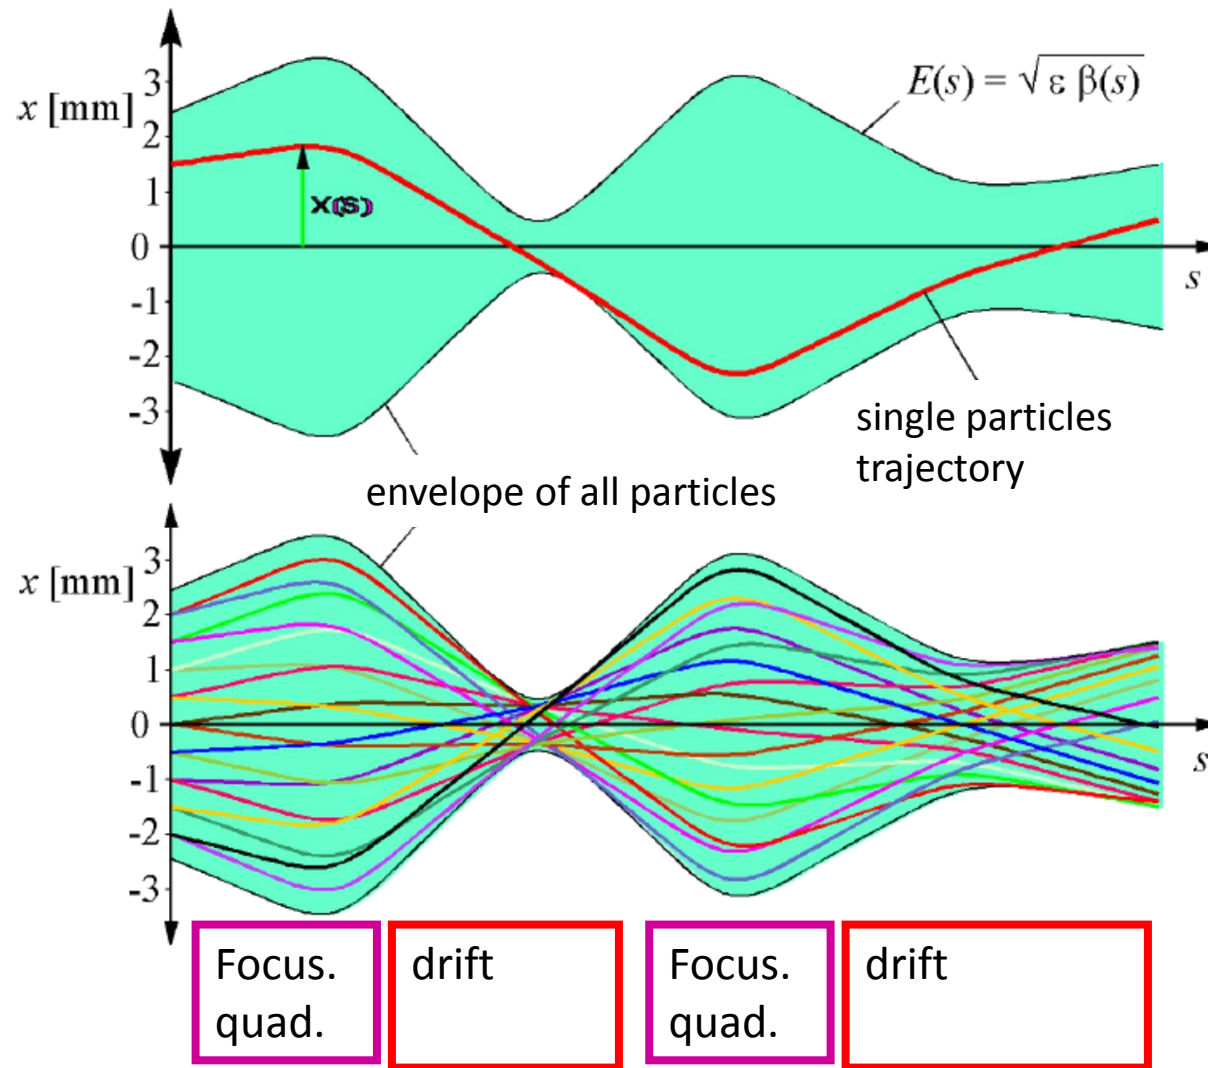

Different devices are used at transfer lines:

- Lower energies  $E_{kin} < 100$  MeV/u: slit-grid device, pepper-pot (suited in case of non-linear forces).
- All beams: Quadrupole variation, 'three grid' method using linear transformations (**not** well suited in the presence of non-linear forces)

**Synchrotron:** lattice functions results in stability criterion

⇒ beam width delivers emittance: 
$$\varepsilon_x = \frac{1}{\beta_x(s)} \left[ \sigma_x^2 - \left( D(s) \frac{\Delta p}{p} \right)^2 \right] \text{ and } \varepsilon_y = \frac{\sigma_y^2}{\beta_y(s)}$$

# Trajectory and Characterization of many Particles

➤ Single particle trajectories are forming a beam

➤ They have a distribution of start positions and angles

⇒ Characteristic quantity is the **beam envelope**

➤ **Goal:**

Transformation of envelope

$\Leftrightarrow$  behavior of whole ensemble  
see lecture of Wolfgang Hillert

Courtesy K.Wille

# Definition of Coordinates and basic Equations

The basic vector is 6 dimensional:

$$\vec{x}(s) = \begin{pmatrix} x \\ x' \\ y \\ y' \\ l \\ \delta \end{pmatrix} = \begin{pmatrix} \text{hori. spatial deviation} \\ \text{horizontal divergence} \\ \text{vert. spatial deviation} \\ \text{vertical divergence} \\ \text{longitudinal deviation} \\ \text{momentum deviation} \end{pmatrix} = \begin{pmatrix} [\text{mm}] \\ [\text{mrad}] \\ [\text{mm}] \\ [\text{mrad}] \\ [\text{mm}] \\ [\text{\%o}] \end{pmatrix}$$

The transformation of a single particle from a location  $s_0$  to  $s_1$  is given by the Transfer Matrix R:

$$\vec{x}(s_1) = R(s) \cdot \vec{x}(s_0)$$

The transformation of a the envelope from a location  $s_0$  to  $s_1$  is given by the Beam Matrix  $\sigma$ :

$$\sigma(s_1) = R(s) \cdot \sigma(s_0) \cdot R^T(s)$$

6-dim Beam Matrix with decoupled hor., vert. and long. plane:

$$\sigma = \begin{pmatrix} \sigma_{11} & \sigma_{12} & 0 & 0 & 0 & 0 \\ \sigma_{12} & \sigma_{22} & 0 & 0 & 0 & 0 \\ 0 & 0 & \sigma_{33} & \sigma_{34} & 0 & 0 \\ 0 & 0 & \sigma_{34} & \sigma_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & \sigma_{55} & \sigma_{56} \\ 0 & 0 & 0 & 0 & \sigma_{56} & \sigma_{66} \end{pmatrix}$$

horizontal  
vertical  
longitudinal  
hor.-long. coupling  
→ 9 values

Beam width for  
the three  
coordinates:

$$x_{rms} = \sqrt{\sigma_{11}}$$

$$y_{rms} = \sqrt{\sigma_{33}}$$

$$l_{rms} = \sqrt{\sigma_{55}}$$

Horizontal  
beam matrix:  
 $\sigma_{11} = \langle x^2 \rangle$   
 $\sigma_{12} = \langle x x' \rangle$   
 $\sigma_{22} = \langle x'^2 \rangle$

# The Emittance for Gaussian and non-Gaussian Beams

The beam distribution can be non-Gaussian, e.g. at:

- beams behind ion source
- space charged dominated beams at LINAC & synchrotron
- cooled beams in storage rings

General description of emittance  
using terms of 2-dim distribution:

It describes the value for 1 standard derivation

$$\varepsilon_{rms} = \sqrt{\underbrace{\langle x^2 \rangle \langle x'^2 \rangle}_{\text{Variances}} - \underbrace{\langle xx' \rangle^2}_{\text{Covariance i.e. correlation}}}$$

For Gaussian beams only:  $\varepsilon_{rms} \leftrightarrow$  interpreted as area containing a fraction  $f$  of ions:

$$\varepsilon(f) = -2\pi\varepsilon_{rms} \cdot \ln(1-f)$$

**Care:**

No common definition  
of emittance concerning  
the fraction  $f$

Emittance $\varepsilon(f)$	Fraction $f$
$1 \cdot \varepsilon_{rms}$	15 %
$\pi \cdot \varepsilon_{rms}$	39 %

$4\pi \cdot \varepsilon_{rms}$	86 %
$8\pi \cdot \varepsilon_{rms}$	98 %

# The Slit-Grid Measurement Device

Slit-Grid: Direct determination of position and angle distribution.

Used for protons with  $E_{kin} < 100 \text{ MeV/u} \Rightarrow \text{range } R < 1 \text{ cm}$ .

## Hardware

## Analysis

**Slit:** position  $P(x)$  with typical width: 0.1 to 0.5 mm

**Distance:** typ. 0.5 to 5 m (depending on beam energy 0.1 ... 100 MeV)

**SEM-Grid:** angle distribution  $P(x')$

# Display of Measurement Results

The distribution is depicted as a function of position [mm] & angle [mrad]

**The distribution can be visualized by**

- Mountain plot
- Contour plot

**Calc. of 2<sup>nd</sup> moments**  $\langle x^2 \rangle$ ,  $\langle x'^2 \rangle$  &  $\langle xx' \rangle$

**Emittance value  $\epsilon_{rms}$  from**

$$\epsilon_{rms} = \sqrt{\langle x^2 \rangle \langle x'^2 \rangle - \langle xx' \rangle^2}$$

⇒ **Problems:**

- Finite **binning** results in limited resolution
- **Background** → large influence on  $\langle x^2 \rangle$ ,  $\langle x'^2 \rangle$  and  $\langle xx' \rangle$

**Or fit of distribution with an ellipse**

⇒ **Effective emittance only**

**Remark:** Behind a ion source the beam might very non-Gaussian due to plasma density and aberration at quadrupoles

**Beam:** Ar<sup>4+</sup>, 60 keV, 15 μA  
at Spiral2 Phoenix ECR source.

P. Ausset, DIPAC 2009

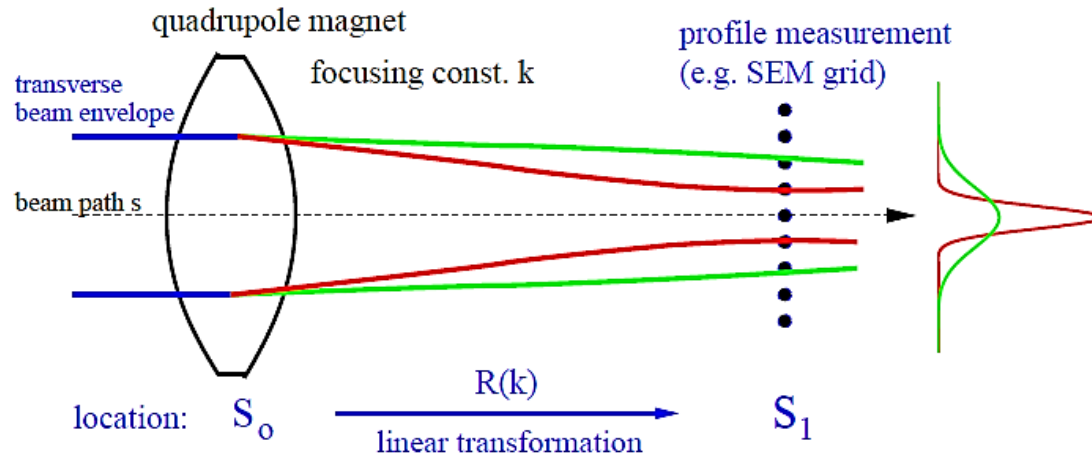

## Outline:

- Definition and some properties of transverse emittance
- Slit-Grid device: scanning method  
scanning slit → beam position & grid → angular distribution
- **Quadrupole strength variation and position measurement**  
**emittance from several profile measurement and beam optical calculation**

# Emittance Measurement by Quadrupole Variation

From a profile determination, the emittance can be calculated via linear transformation, if a well known and constant distribution (e.g. Gaussian) is assumed.

- Measurement of beam width

$$x_{max}^2 = \sigma_{11}(1, k)$$

matrix  $R(k)$  describes the focusing.

- With the drift matrix the transfer is

$$R(k_i) = R_{\text{drift}} \cdot R_{\text{focus}}(k_i)$$

- Transformation of the beam matrix

$$\sigma(1, k_i) = R(k_i) \cdot \sigma(0) \cdot R^T(k_i)$$

**Task: Calculation of  $\sigma(0)$**

**at entrance  $s_0$  i.e. all three elements**

measurement:

$$x^2(k) = \sigma_{11}(1, k)$$

# Measurement of transverse Emittance

Using the 'thin lens approximation' i.e. the quadrupole has a focal length of  $f$ :

$$R_{focus}(K) = \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ K & 1 \end{pmatrix} \Rightarrow R(L, K) = R_{drift}(L) \cdot R_{focus}(K) = \begin{pmatrix} 1 + LK & L \\ K & 1 \end{pmatrix}$$

Measurement of the matrix-element  $\sigma_{11}(1, K)$  from  $\sigma(1, K) = R(K) \cdot \sigma(0) \cdot R^T(K)$

**Example:** Square of the beam width at  
ELETTRA 100 MeV  $e^-$  Linac, YAG:Ce:

G. Penco (ELETTRA) et al., EPAC'08

**For completeness:** The relevant formulas

$$\begin{aligned} \sigma_{11}(1, K) &= L^2 \sigma_{11}(0) \cdot K^2 \\ &\quad + 2 \cdot (L \sigma_{11}(0) + L^2 \sigma_{12}(0)) \cdot K \\ &\quad + L^2 \sigma_{22}(0) + \sigma_{11}(0) \\ &\equiv a \cdot K^2 - 2ab \cdot K + ab^2 + c \end{aligned}$$

The three matrix elements at the quadrupole:

$$\sigma_{11}(0) = \frac{a}{L^2}$$

$$\sigma_{12}(0) = -\frac{a}{L^2} \left( \frac{1}{L} + b \right)$$

$$\sigma_{22}(0) = \frac{1}{L^2} \left( ab^2 + c + \frac{2ab}{L} + \frac{a}{L^2} \right)$$

$$\epsilon_{rms} \equiv \sqrt{\det \sigma(0)} = \sqrt{\sigma_{11}(0) \cdot \sigma_{22}(0) - \sigma_{12}^2(0)} = \sqrt{ac} / L^2$$

# Summary for transverse Emittance Measurement

Emittance is the important quantity for comparison to theory.

It includes size (value of  $\epsilon$ ) and orientation in phase space ( $\sigma_{ij}$  or  $\alpha$ ,  $\beta$  and  $\gamma$ )

three independent values  $\epsilon_{rms} = \sqrt{\sigma_{11} \cdot \sigma_{22} - \sigma_{12}^2} = \sqrt{\langle x^2 \rangle \cdot \langle x'^2 \rangle - \langle xx' \rangle^2}$

assuming no coupling between horizontal, vertical and longitudinal planes

**Transfer line, low energy beams → direct measurement of x- and x'-distribution:**

➤ **Slit-grid:** movable slit →  $x$ -profile, grid →  $x'$ -profile

**Transfer line, all beams → profile measurement + linear transformation:**

➤ **Quadrupole variation:** one location, different setting of a quadrupole

**Assumptions:** ➤ well aligned beam, no steering

➤ no emittance blow-up due to space charge

**Remark:** non-linear transformation possible via tomographic reconstruction

**Important remark:** For a synchrotron with a *stable beam storage*,

width measurement is sufficient using  $x_{rms} = \sqrt{\epsilon_{rms} \cdot \beta}$

# Measurement of longitudinal Parameters

## Measurement of longitudinal parameter:

Bunch length measurement at

- Synchrotron light sources
- Linear light sources
- Summary

### Longitudinal ↔ transverse correspondences:

- |                             |                             |
|-----------------------------|-----------------------------|
| ➤ position relative to rf   | ↔ transverse center-of-mass |
| ➤ bunch structure in time   | ↔ transverse profile        |
| ➤ momentum or energy spread | ↔ transverse divergence     |
| ➤ longitudinal emittance    | ↔ transverse emittance.     |

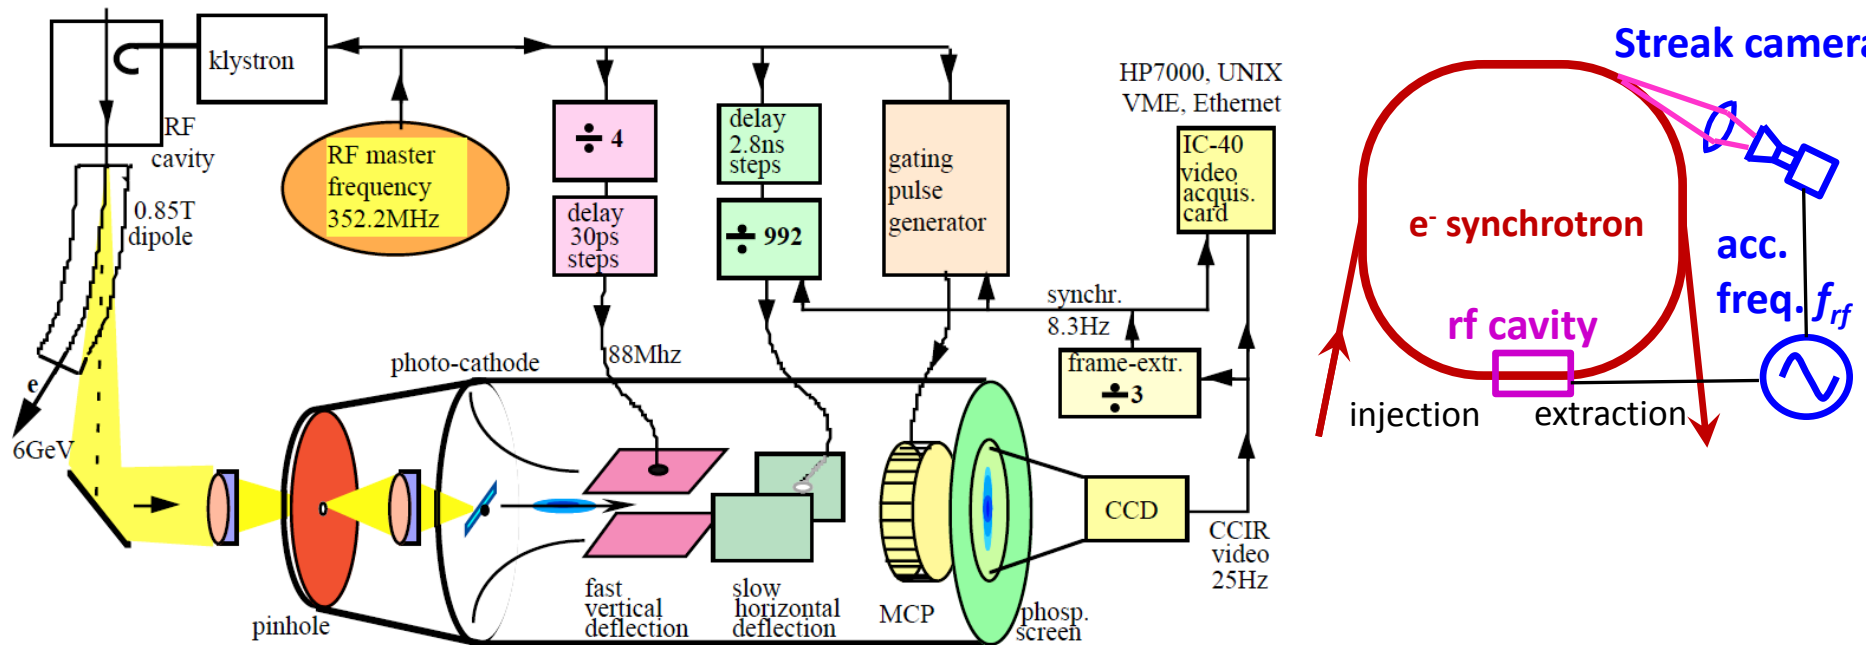

# Bunch Length Measurement for relativistic Electrons

Electron bunches are too short ( $\sigma_t < 100$  ps) to be covered by the bandwidth of pick-ups ( $f < 3$  GHz  $\Leftrightarrow t_{rise} > 100$  ps) for structure determination.

→ Time resolved observation of synchr. light with a streak camera: Resolution  $\approx 1$  ps.

## Scheme of a streak camera

# Technical Realization of a Streak Camera

Hardware of a streak camera

Time resolution down to 0.5 ps:

# Technical Realization of a Streak Camera

Hardware of a streak camera

Time resolution down to 0.5 ps:

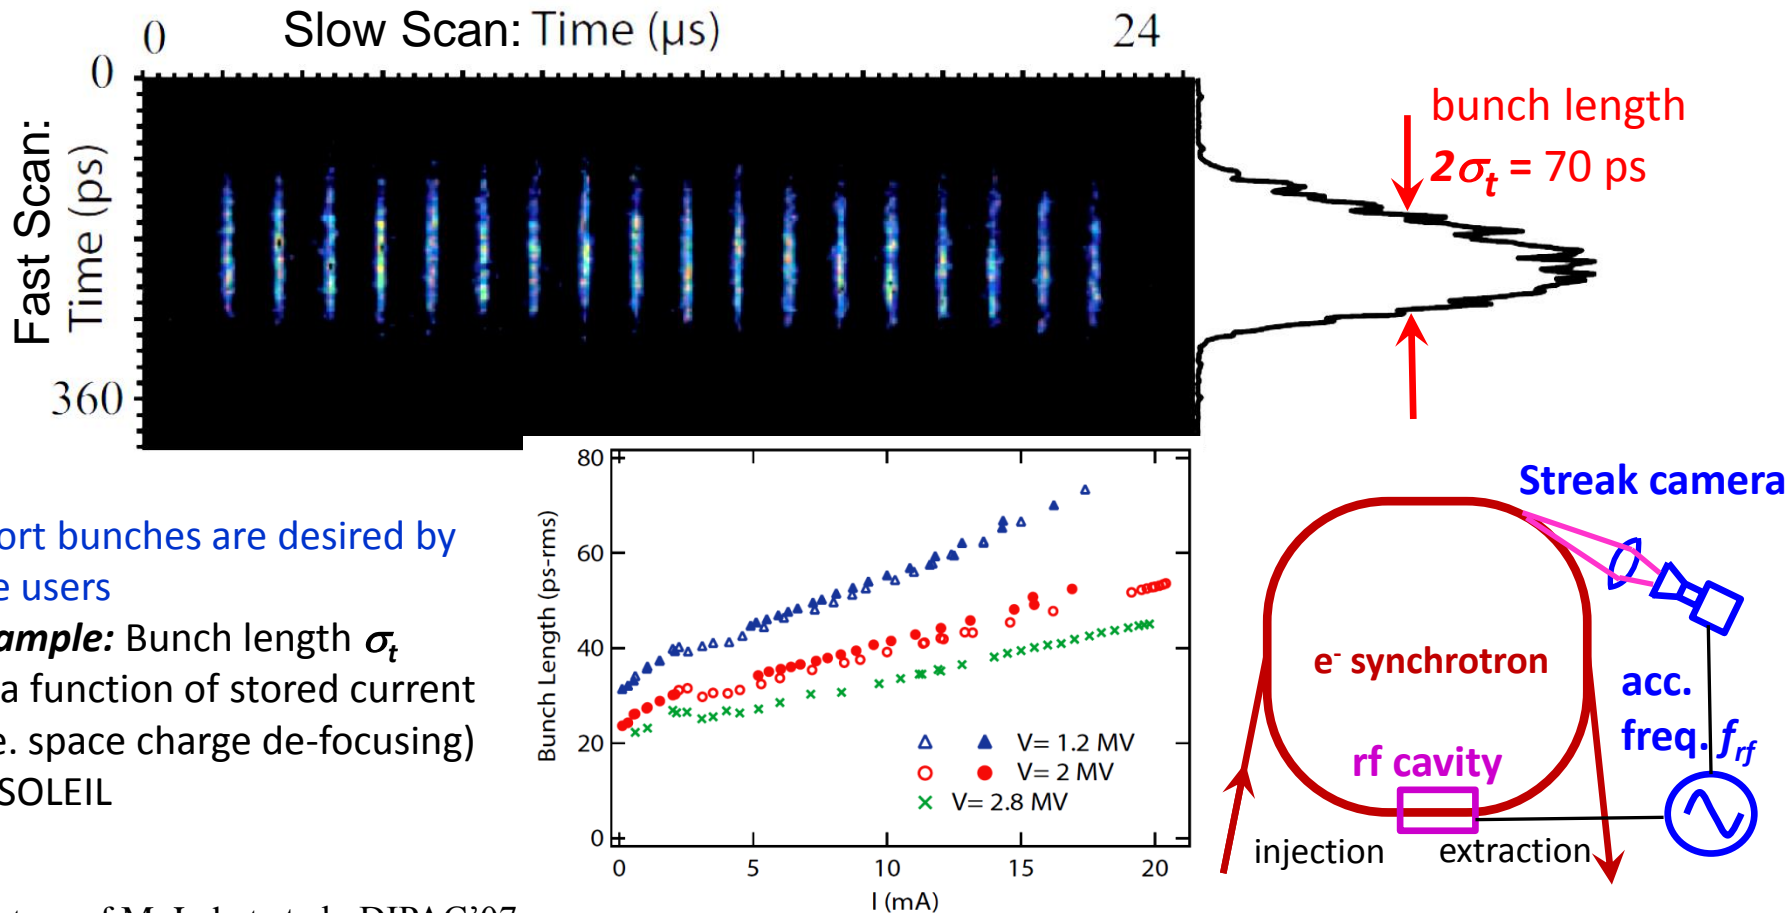

# Results of Bunch Length Measurement by a Streak Camera

The streak camera delivers a fast scan in vertical direction (here 360 ps full scale) and a slower scan in horizontal direction (24  $\mu$ s).

**Example:** Bunch length at the synchrotron light source SOLEIL for  $U_{rf} = 2$  MV  
for slow direction 24  $\mu$ s and scaling for fast scan 360 ps: measure  $\sigma_t = 35$  ps.

## FARADAY CUP 1998

**Purpose.** To recognize and encourage innovative achievements in the field of accelerator beam instrumentation.

**Award.** The Faraday Cup Award consists of a US\$ 5000 prize and a certificate to be presented at the next Beam Instrumentation Workshop. Winners participating in the BIW will be given a \$1000 travel allowance.

**Eligibility.** Nominations are open to contributors of all nations regardless of the geographical location at which the work was done. The Award goes normally to one person, but may be shared by recipients having contributed to the same accomplishment. It will normally be awarded to scientists in the early stage of their career. Nominations of candidates shall remain active for 2 competitions.

**Establishment and support.** The Award was established in 1991 with the support of the Beam Instrumentation Workshop Organizing Committee.

**Rules.** The Faraday Cup shall be awarded for an outstanding contribution to the development of an innovative beam diagnostics instrument of proven workability. The Faraday Cup is only awarded for published contribution and delivered performance—as opposed to theoretical performance. Rules are available on request.

**Award Committee:** The Beam Instrumentation Workshop Organizing Committee.

**Nominations.** The nomination package shall include the name of the candidate, relevant publications, a statement outlining his/her personal contribution and that of others, two letters from co-workers familiar with the candidate and his contribution. Two master copies suitable for photocopying of this package must be submitted not later than the 15th of November 1997 to Steven Smith c/o BIW'98 Secretariat, SLAC, Stanford University, Stanford CA 94305-4085, U.S.A..

# Bunch Length Measurement by electro-optical Method

For Free Electron Lasers → bunch length below 1 ps is achieved

- Below the resolution of streak camera
- Short laser pulses with  $t \approx 10 \text{ fs}$  and electro-optical modulator

**Electro optical modulator:** birefringent, rotation angle depends on external electric field

Relativistic electron bunches: transverse field  $E_{\perp, lab} = \gamma E_{\perp, rest}$  carries the time information

Scanning of delay between bunch and laser → time profile after several pulses.

From S.P.Jamison et al., EPAC 2006

# Bunch Length Measurement by electro-optical Method

For Free Electron Lasers → bunch length below 1 ps is achieved

Short laser pulse  $\Leftrightarrow$  broad frequency spectrum (property of Fourier transformation)

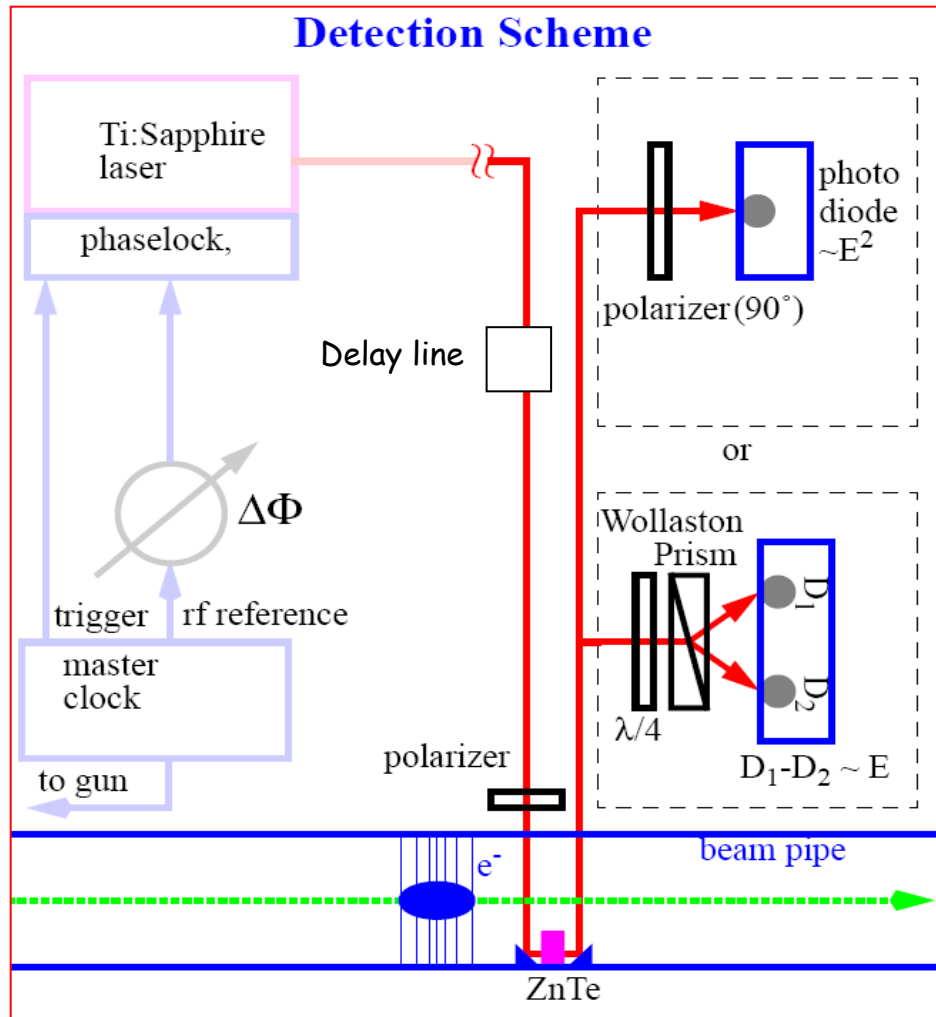

**Optical stretcher:** Separation of colors by different path length  $\Rightarrow$  **single-shot observation**

Courtesy S.P.Jamison et al., EPAC 2006

# Realization of EOS Scanning

Setup of a scanning EOS method.

Using 12fs pulses from  
 Ti:A<sub>12</sub>O<sub>3</sub> laser at 800nm and  
 ZnTe crystal 0.5mm thick  
 with a e<sup>-</sup> - beam 46MeV of 200pC

X. Yan *et al*, Phys. Rev. Lett. 85, 3404 (2000)

# Hardware of a compact EOS Scanning Setup

**Example:** Bunch length at FLASH  
100 fs bunch duration = 30  $\mu\text{m}$  length

B. Steffen et al, DIPAC 2009

B. Steffen et al., Phys. Rev. AB 12, 032802 (2009)

Devices for bunch length at light sources:

## *Streak cameras:*

- Time resolved monitoring of synchrotron radiation
  - for relativistic  $e^-$ -beams,  $t_{\text{bunch}} < 1 \text{ ns}$
  - reason: too short bunches for rf electronics.

## *Laser scanning:*

- Electro-optical modulation of short laser pulse
  - very high time resolution down to some fs

## Slow extraction is frequently used at the GSI synchrotrons.

- It is a quite complex, i.e. interesting beam physics process
- The timer dependence on the 100  $\mu$ s time scale should be improved

### Tasks:

- New particle detectors have to be developed, here fast counting with diamond detector
  - Experimental tests of improvements
  - Modeling by MADX of extraction process
- PhD position at GSI in collaboration with University Frankfurt

Single-crystal  
(Element Six)

**Diagnostics is the 'sensory organ' for the beam.**

**It required for operation and development of accelerators**

**Several categories of demands leads to different installations:**

- Quick, non-destructive measurements leading to a single number or simple plots
- Complex instrumentation used for hard malfunction and accelerator development
- Automated measurement and control of beam parameters i.e. feedback

**The goal and a clear interpretation of the results is a important design criterion.**

**General comments:**

- Quite different technologies are used, based on various physics processes
- Accelerator development goes parallel to diagnostics development

**Thank you for your attention!**

# Conclusion for Beam Diagnostics Course

**Thank you for your attention!**

For a successful construction and operation of an accelerator,  
the understand and right balance of all disciplines is required!

# Emittance Enlargement by Injection Mis-steering

Emittance conservation requires precise injection matching

Wrong angle

of injected beam:

- injection into outer phase space → large  $\beta$ -amplitude i.e. large beam
- might result in 'hollow' beam
- filling of acceptance i.e. loss of particles

⇒ Hadron beams: larger emittance after acceleration

Example: Variation of vertical injection angle by magnetic steerer  
Beam:  $C^{6+}$  at 6.7 MeV/u acc. to 600 MeV/u, up to  $6 \cdot 10^9$  ions per fill with multi-turn injection, IPM integration 0.5 ms i.e.  $\approx 100$  turns

Vertical profile at injection:

Vertical profile after acc.:

Horizontal profile at injection:

Horizontal profile after acc.:

misplace injection

filamentation

larger emittance

Schematic simulation:  
Courtesy M. Syphers

## Ideal case of injection matching:

Orientation of injected beam matches

phase space as given by synchrotron

Twiss parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  i.e. 'machine emittance'

$\Leftrightarrow$  no change after each turn  $\Leftrightarrow$  stable storage

$\Leftrightarrow$  The beam ellipse  $\sigma_{beam}$  correspond to the machine ellipse at injection point for  $N=0$  i.e.

$$\sigma_{beam}(N=0) = \varepsilon_{beam} \begin{pmatrix} \beta_{synch} & -\alpha_{synch} \\ -\alpha_{synch} & \gamma_{synch} \end{pmatrix}$$

$\Rightarrow$  **only in this case stable storage** (math:  $t \rightarrow \infty$ )

$$\sigma_{beam}(N=0) = \sigma_{beam}(N \rightarrow \infty)$$

## Ideal case of injection matching:

Orientation of injected beam matches

phase space as given by synchrotron

Twiss parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  i.e. 'machine emittance'

$\Leftrightarrow$  no change after each turn  $\Leftrightarrow$  stable storage

## Mismatched case:

➤ The beam ellipse  $\sigma_{beam}$  has different orientation as machine ellipse at injection point for  $N=0$  i.e.

➤ Transformation after one turn

$$\sigma_{beam}(N=1) = \mathbf{M} \sigma_{beam}(N=0) \mathbf{M}^T \neq \sigma_{beam}(N=0)$$

i.e. rotation in phase space by the tune

i.e. phase advance per turn

Depictive argument: A particle on both ellipses

**Observable quantity:** Beam profile oscillates

**After many turns:**

Particle have different tunes e.g. by longitudinal momentum deviation and chromaticity  $\frac{\Delta Q}{Q_0} = \xi \cdot \frac{\Delta p}{p_0}$

or space charge  $\Delta Q_{incoh} \Rightarrow$  Entire transverse phase space is filled i.e. beam with enlarged emittance

# Injection Matching into a Synchrotron: Phase Space Mismatch

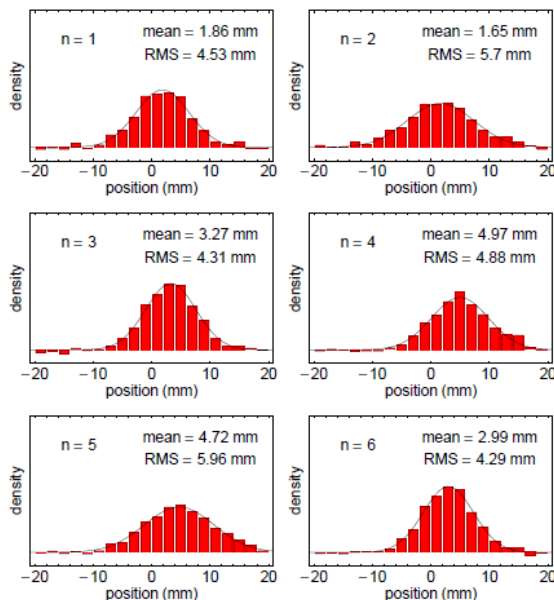

## Mis-matched injection into a synchrotron:

### Can be monitored by beam profile measurement:

**Example:** Injection of a 80 ns bunch of protons into CERN PS at 1.4 GeV/u (2.2  $\mu$ s revolution time)

Profile measurement by SEM-Grid

- Turn-by-turn profile variation related to tune
- Used for improvement of injection parameters

From M. Benedikt et al., DIPAC 2001

# Coherent Optical Transition Radiation

Observation of coherent OTR for **compressed** bunches at LINAC based light sources

**Reason:** Coherent emission **if** bunch length  $\approx$  wavelength ( $t_{bunch}=2\text{ fs} \Leftrightarrow l_{bunch}=600\text{ nm}$ )

**or** bunch fluctuations  $\approx$  wavelength

**Parameter reach**

**for most LINAC-based FELs!**

Beam parameter: FLASH, 700 MeV,

0.5 nC, with bunch compression

*OTR screen*

*scint. screen*

(a) OTR screen

(c) LuAG screen

(b) OTR screen, +100ns delay

(d) LuAG screen, +100ns delay

**prompt** emission for OTR and scint. screen

→ **coherent and in-coherent OTR**

**100 ns delayed** emission

→ no OTR as expected (classical process)

→ emission by scint. screen due to lifetime

$\Leftrightarrow$  correct profile image!
