# BEER

THE REASON  
I WAKE UP  
EVERY  
AFTERNOON

# Why Should You Care?

@ ... **Accelerators Generate Radiation!!!**

@ Radiation (can) impacts:

@ People

@ Materials, accelerator components,  
electronics,...

@ Operation

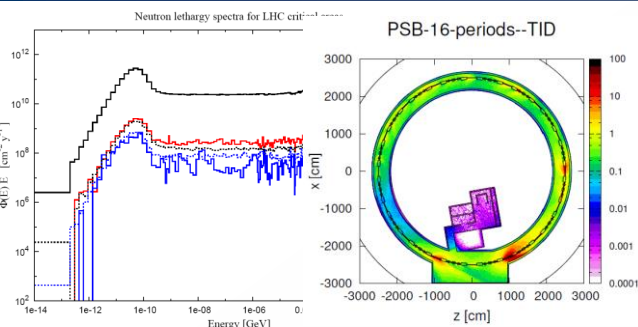

In this sense:

@ Radiation (more and more!!!) determines the way  
how we have to design **installations, accelerator  
components & plan for shutdowns, ...**

# The “Victims”

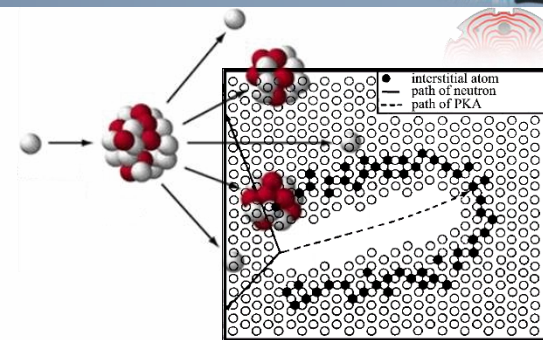

- @ Beam Intercepting Devices  
(Collimators, Scrapers, Dumps, etc.)
- @ Magnets (Insulators, etc.)
- @ Vacuum equipment
- @ Other beam-line elements
- @ Cables and optical Fibres
- @ Electronics (components & systems)
- @ Super-Conducting magnets/links/cavities/...
- @ ...
- @ All exposed parts at varying radiation levels

# What Do We Need?

# LHC as an Example

**LHC is a proton-proton (or ion/ion) collider**

- ❑ 2 proton beams at 7 TeV of  $3 \times 10^{14}$   $p^+$  each
- ❑ Stored for 10-20 hours in collision
- ❑ Total stored energy of **0.7 GJ**  
Sufficient to melt **1 ton of Cu**
- ❑ ~5000 superconducting magnets

- ❑ Tiny fractions (few mJ) of the stored beam suffice to **quench a superconducting magnet** or even to **destroy parts of the accelerators**.
- ❑ Single particles can impact essential electronics and **stop operation**
- ❑ Radiation **deteriorates surrounding materials and equipment** – **repair & maintenance**

SLAC: ~0.5MJ 16 GeV electrons

## Vacuum system PLC (LHC\_UJ76)

P. Supply 24VDC 5A

# **Radiation & Quantities of Concern**

**a quick re-cap from  
Francesco's Presentation**

# Material Damage

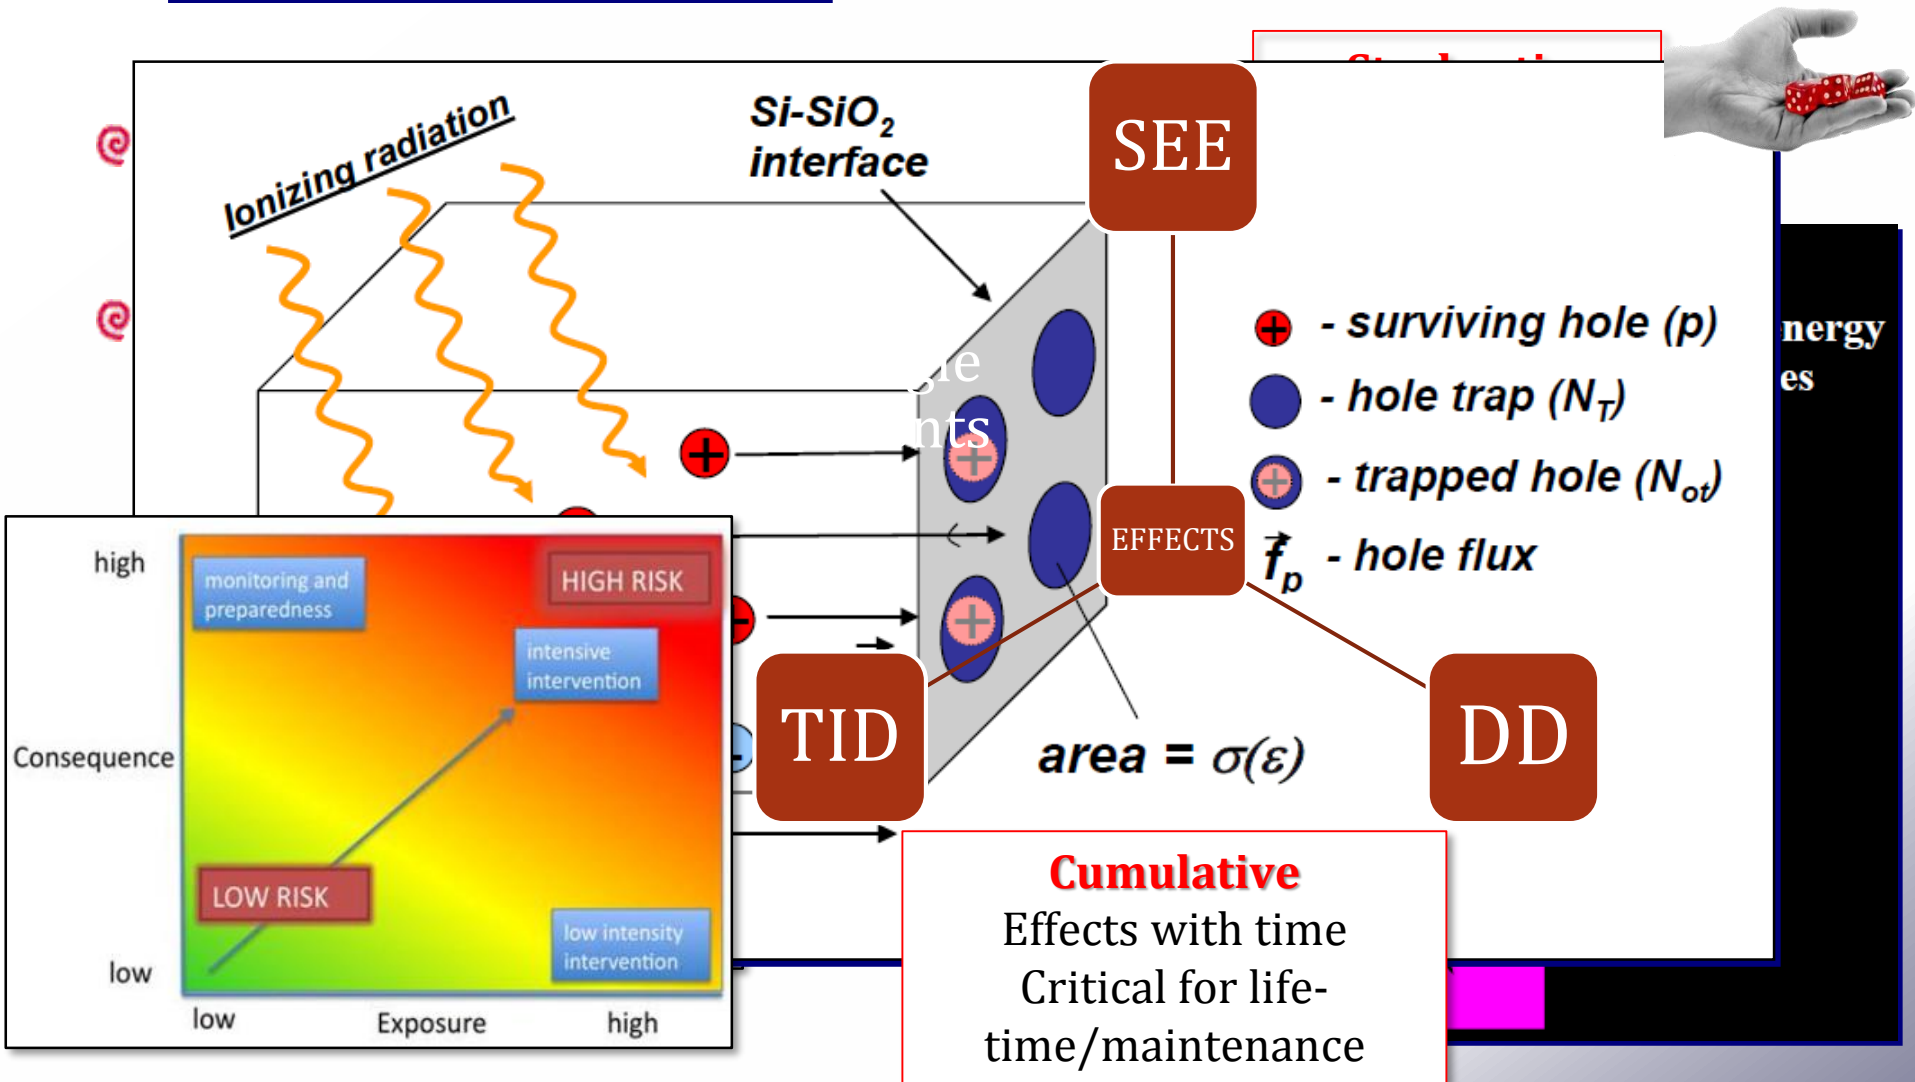

There are several physical mechanisms which can result in damage to the target material. They are related to:

- ⌚ **Ionizing energy losses/heating**, mostly connected to the electronic **stopping power**
- ⌚ **Non ionizing energy losses (NIEL)**, mostly due to energy transfer to **atomic nuclei**. They can typically result in displacement damage to the crystalline/metallic structure of the target material
- ⌚ **Gas production**, mostly due to protons, deuterons, tritons,  $^3\text{He}$  and alphas **stopping in the target**. They can be beam particles ranging out in the target (low energy beams), or secondary particles produced by nuclear interactions in the target itself

**Exposure is the process when a material is exposed to some kind of radiation**

- ④ Measures for the amount of exposure
  - ④ **Dose**: amount of energy deposited by radiation per mass  
[units of Energy/mass  $1\text{Gy} = 1\text{J/kg}$ ,  $1\text{Gy} = 100\text{rad}$ ]
  - ④ **Dose rate**: Dose delivered in a given time  
[units of Energy/(mass x time),  $\text{Gy/s}$ ,  $\text{Gy/h}$ ,  $\text{Gy/y}$ ]
  - ④ **Fluence**: amount of energetic particle per unit area  
[units of particles/area i.e.  $1/\text{area}$ ,  $\text{cm}^{-2}$ ,  $\text{m}^{-2}$ ]
  - ④ **Flux**: Fluence delivered in a given time  
[units of particles/(area x time) i.e.  $1/(\text{area} \times \text{time})$ ,  $\text{cm}^{-2}\text{s}^{-1}$ , ...]
- ④ **Activity**: amount of radiation produced by a radioactive sample

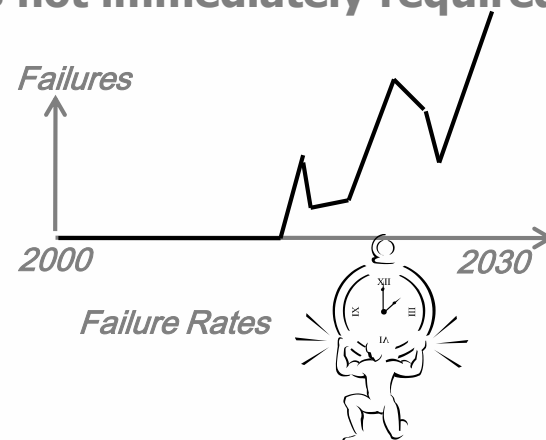

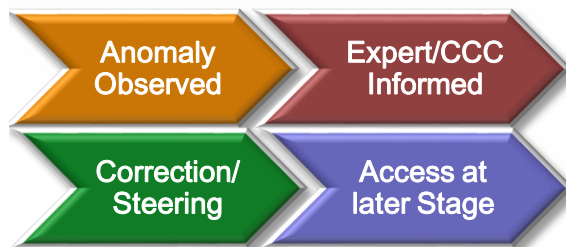

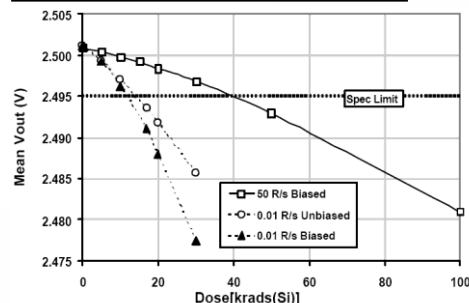

## ☉ Total Ionizing Dose (TID):

## ⚡ TID + Displacement Damage

- ☺ Devices get slowly out of tolerance  
(final failure can often be anticipated; access not immediately required)
- ☺ No 'early' failures (due to radiation)

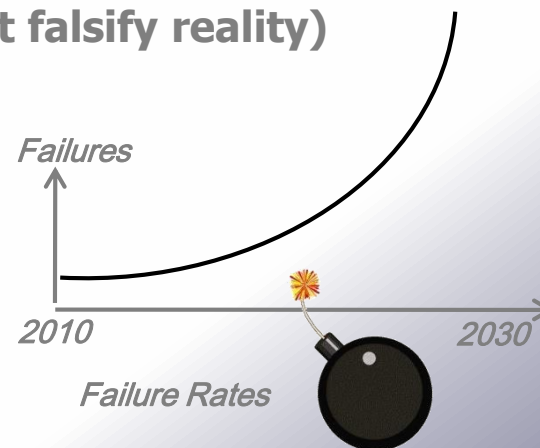

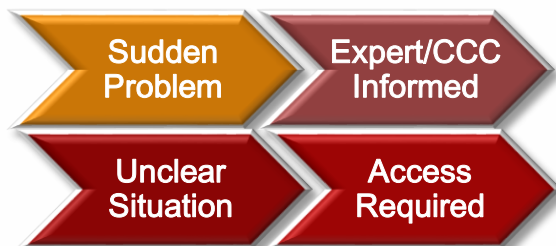

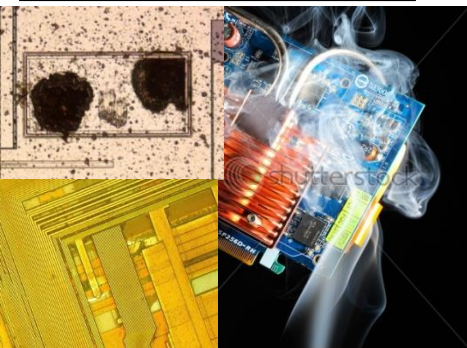

### Possible Scenario:

## ⚡ Single Event Effects

- ☹ Failures will appear and rapidly increase in frequency  
(destructive failures possible; access often required)
- ☹ 'Early Operation' problem (observation might falsify reality)

### Possible Scenario:

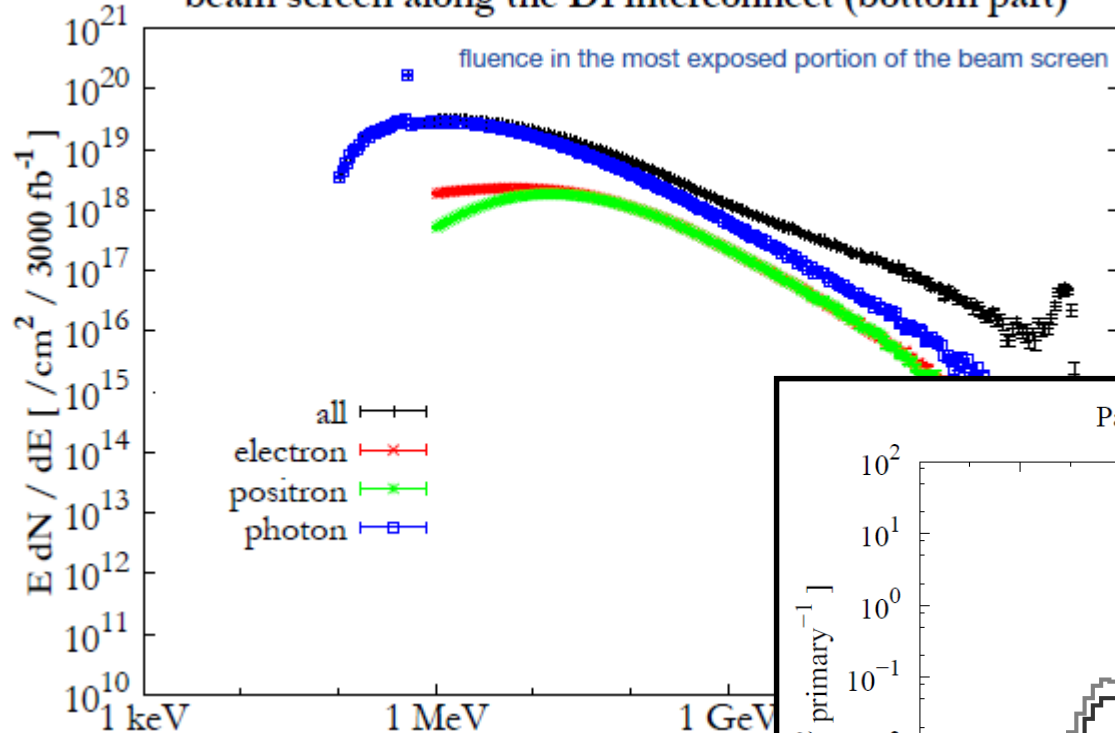

# **Radiation Environment**

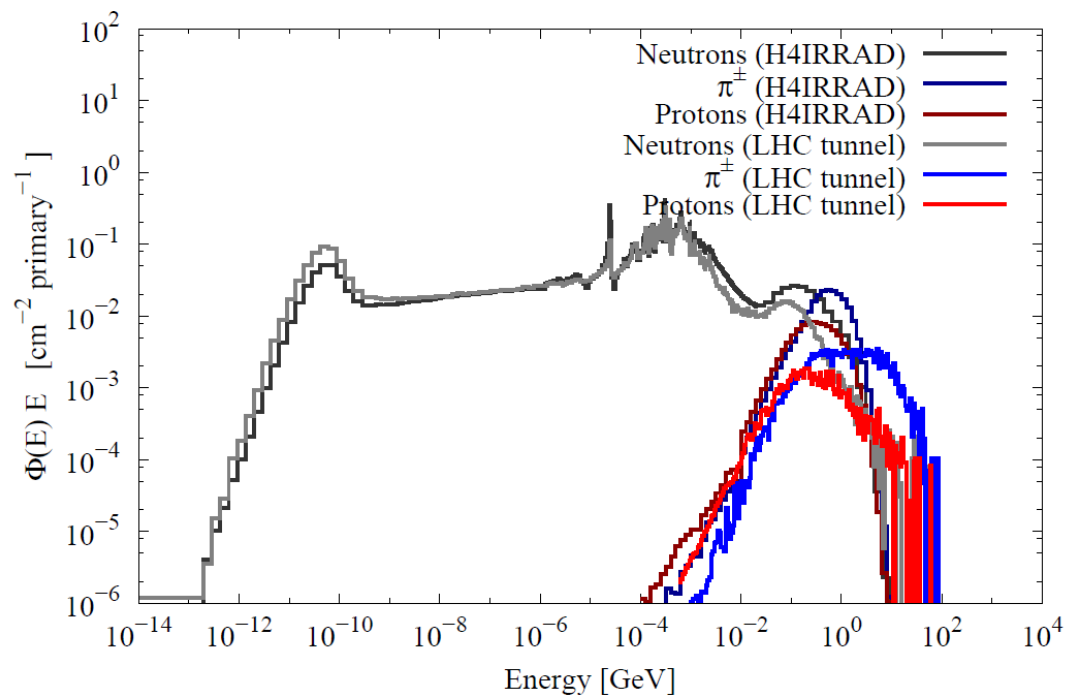

**already mostly covered in  
Francesco's Talk**

# Radiation Environment

# Particle Type & Energy Matter

## • Displacement Damage function

- Normalization of radiation fields to 1 MeV neutron equivalent damage ( $n_{eq}$ )

$$\Phi_{eq} = \kappa_x \Phi_x$$

$$\kappa_p = [0.52..0.62] \text{ (24 GeV/c protons)}$$

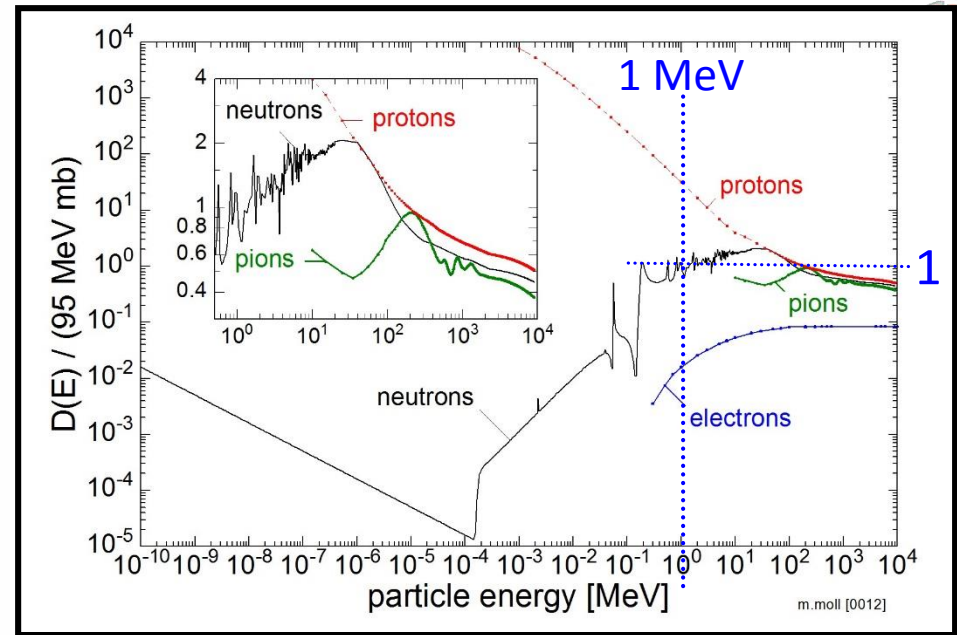

$$\kappa_p = 1.85 \text{ (26 MeV protons)}$$

$$\kappa_\pi = 1.14 \text{ (300 MeV pions)}$$

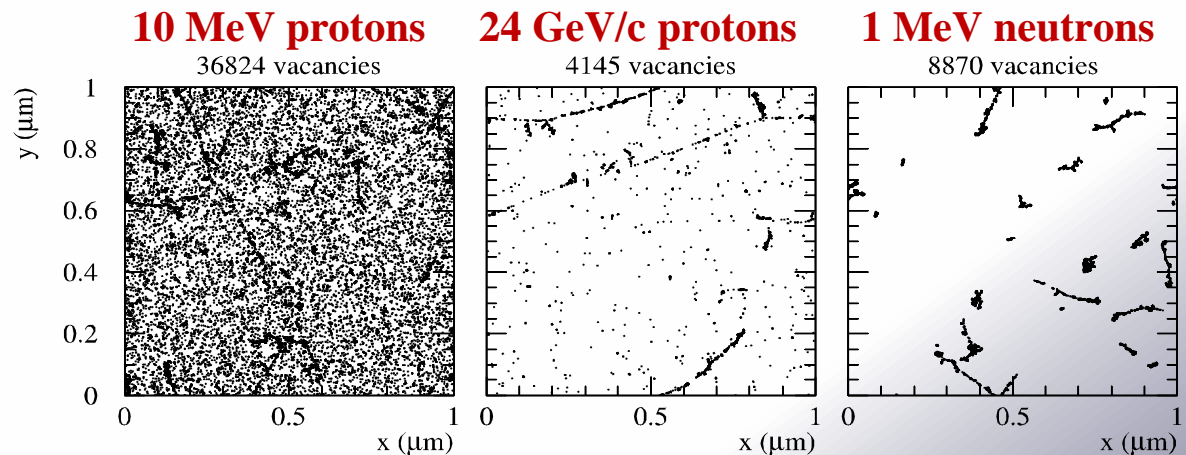

$$\kappa_n = 0.92 \text{ (TRIGA reactor neutrons)}$$

## • NIEL Hypothesis:

- Assumption: NIEL scaling of damage parameters
- Applied to predict damage of radiation fields in HEP
- NIEL violation observed:
  - Material dependence
  - Proton vs. neutron damage
  - ...

[Data: A.Vasilescu and G.Lindstroem]

[M.Huhtinen, NIMA 491(2002), 194]

**Simulation:** Vacancies in  $(1\mu\text{m})^3$  after  $10^{14}$  particles/cm<sup>2</sup>

# DD – is it Natural?

**Cascades in our life  
(people: skating-ring)**

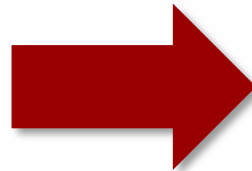

**Cascades in our life  
(animals)**

**Cascade under applied stress**

# Mechanical Parameters

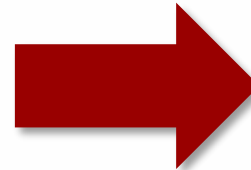

- @ Strong
- @ Ductile
- @ High thermal conductivity
- @ Stable
- @ Safe

- @ Weak
- @ Brittle
- @ Low thermal conductivity
- @ Unstable
- @ Dangerous

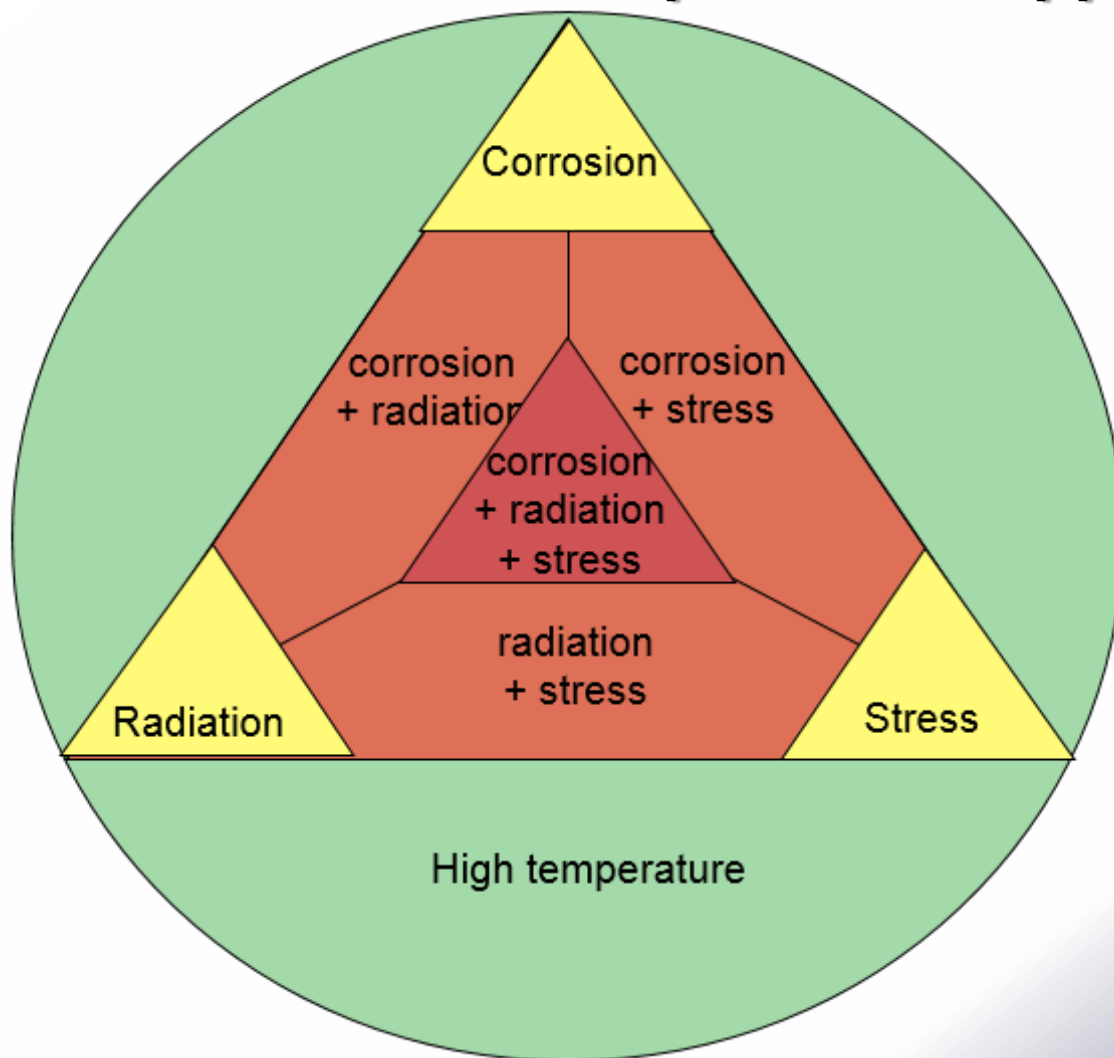

+

# Other – linked - Parameters

**Radiation effects and consequences have to be seen in the full context of the particular application!**

# Material Examples

## Plastics

- @ cable insulations, structural components, lamps, electrical cubicles..
- @ **Plastics are organic materials**
- @ They are derived from petroleum or other natural materials (resins, monomers, etc.)
- @ Contain Carbon

## Effect of radiation:

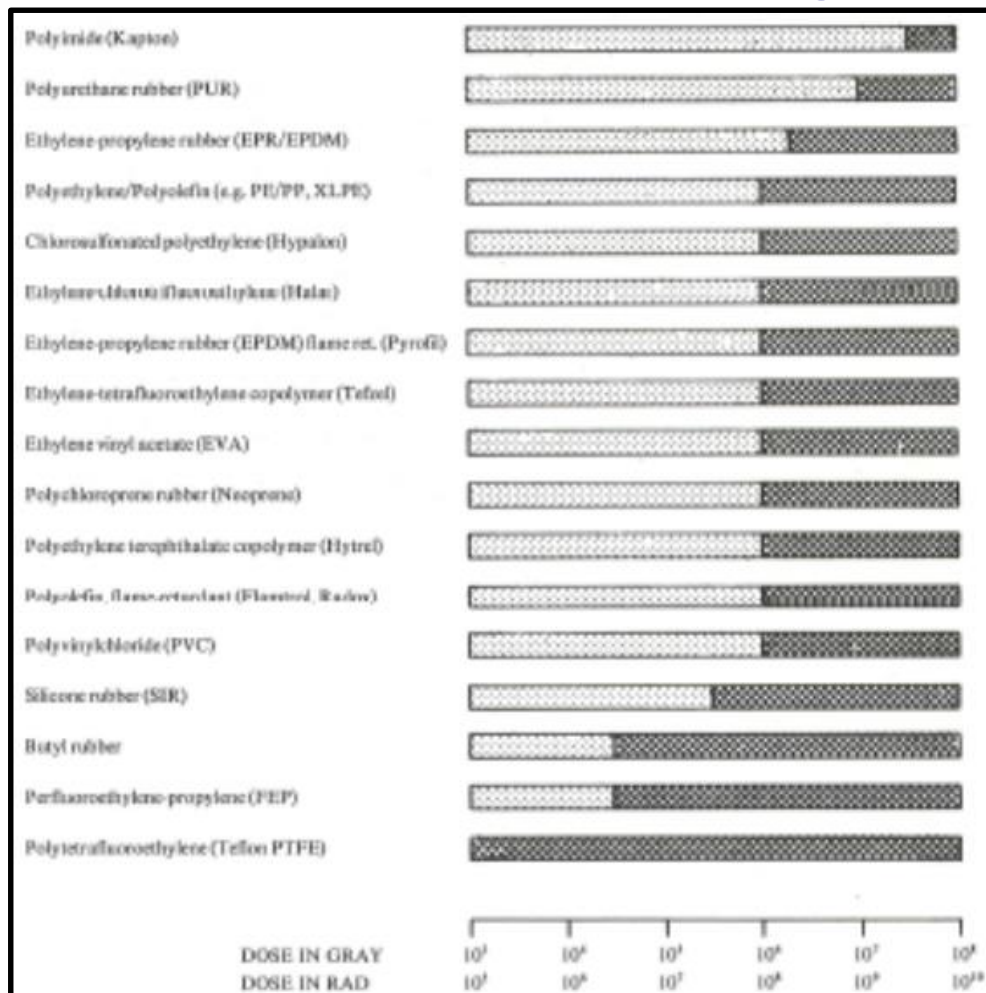

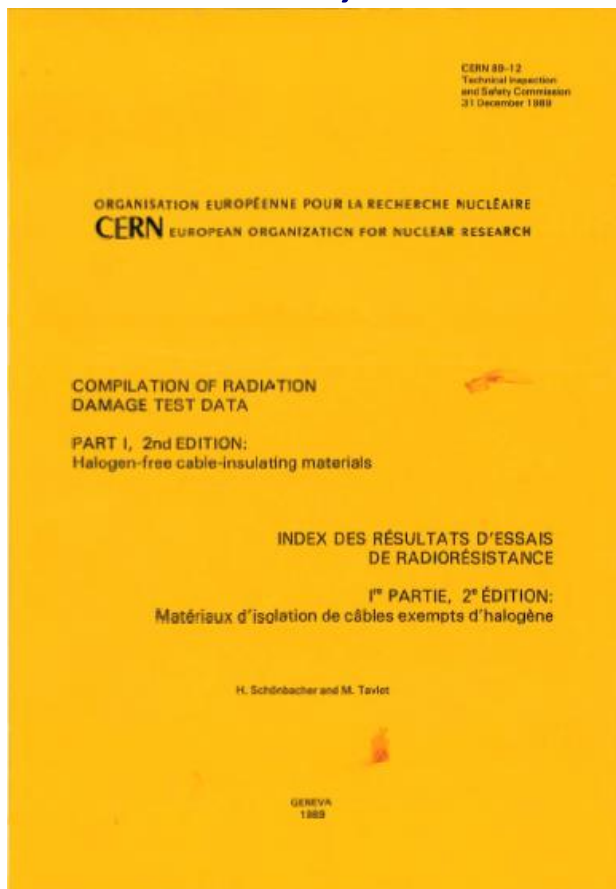

- @ **Degradation of mechanical properties** (e.g. reduced elongation at break)
- @ **Degradation of electrical properties**

# Material Examples

## Plastics

@ useful information in CERN's Yellow books (e.g. CERN 82-10, or 89-12)

# Material Examples

## Halogens

⊗ Most electronegative elements:  
easily gain an electron

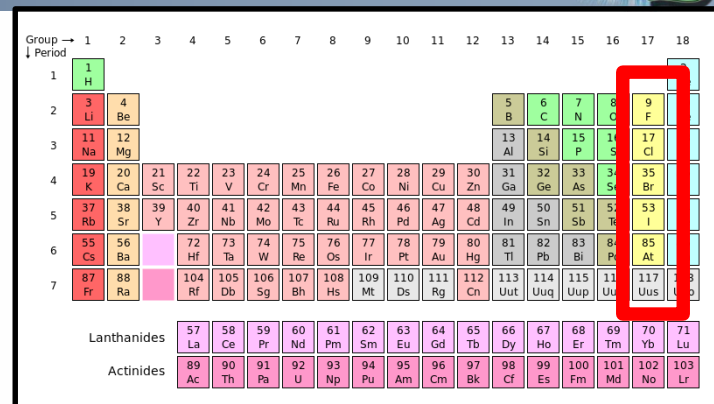

⊗ **chemically active!**

⊗ For this reason, in sufficient quantities they can be  
extremely dangerous

⊗ Chlorine is the most common on earth

⊗ becomes aggressive and attacks metallic surfaces

⊗ Fluorine even glass!!!

The periodic table shows elements grouped by columns (Groups 1-18) and rows (Periods 1-7). The halogens are located in Group 17. A red box highlights the elements Fluorine (F), Chlorine (Cl), Bromine (Br), Iodine (I), and Astatine (At) in the 17th column.

**What's also needed: -> Moisture**

⊗ Leaking magnet cooling circuits, water valves, etc.

⊗ Infiltration from the tunnel ceiling

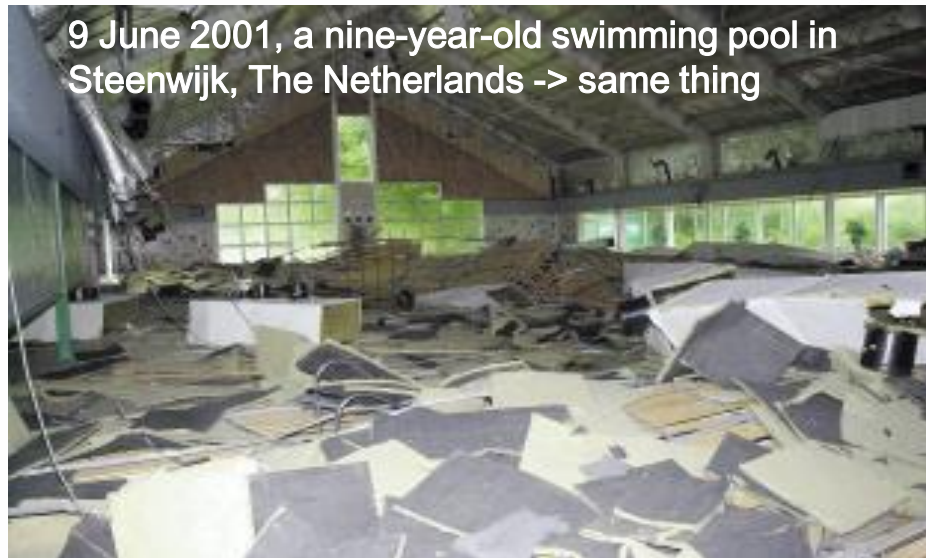

# Material Examples

## Two “Famous” Examples

9 May 1985: suspended ceiling at Uster indoor swimming pool collapsed

9 June 2001, a nine-year-old swimming pool in Steenwijk, The Netherlands -> same thing

## @ & at Accelerators:

# Material Examples

## PVC as a bad example

@ PVC = Polyvinyl Chloride

@ Usually one worries about 'burning' them:

### Health and safety

[edit]

PVC is a useful material because of its inertness and this inertness is the basis of its low toxicity: "There is little evidence that PVC powder itself causes any significant medical problems."<sup>[7]</sup> The main health and safety issues with PVC are associated with "VCM", its carcinogenic precursor, the products of its incineration (dioxins under some circumstances), and the additives mixed with PVC, which include heavy metals and potential endocrine disruptors. "Fear of litigation ... have all but eliminated fundamental research into VCM polymerization."<sup>[7]</sup>

Probably the greatest impact of PVC on health and safety have been highly positive. It has revolutionized the safe handling of sewage and, being affordable, its use is widespread outside of developed countries.<sup>[7]</sup>

@ PVC and Halogens are NOT allowed in confined space, tunnels etc.

@ AND **with radiation**: Dehydrochlorination is the major mechanism of PVC degradation by X and  $\gamma$ -rays

@ **Cl<sup>-</sup> ions react with water droplets and create a very corrosive environment**

# Material Examples

## Halogens

- ⊗ **Water droplets charged with  $\text{Cl}^-$  ions** can fall onto accelerator components, generating stress corrosion cracking in unprotected stainless steel components
- ⊗ Few droplets, maybe a single one, are enough to generate corrosion and failure
- ⊗ **Once corrosion is there it cannot be passivated anymore!!!**

# Material Examples

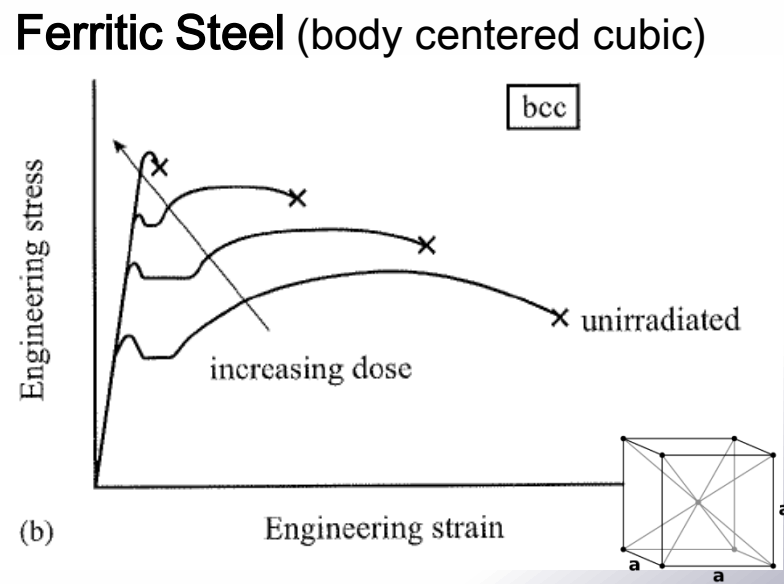

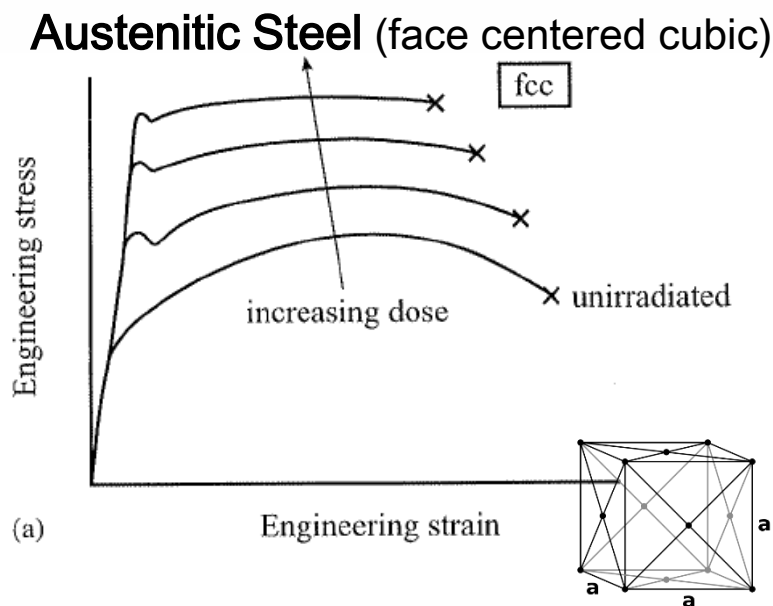

## **Metals** (studies driven by reactor applications)

- ⌚ Mechanical (macroscopic) effects, are ultimately caused by formation of **defects in the lattice structure**
- ⌚ Defects are : voids, gas bubbles, dislocations...
- ⌚ **Temperature** has an effect:
  - ⌚ **Annealing** increases the mobility of defects
    - ⌚ Often positive impact by reconstructing the lattice
    - ⌚ BUT sometimes accelerates defects  
(especially if the material is subject to high stresses)
- ⌚ **Hardness**: resistance of a material to permanent (plastic) deformation under an given load curve
- ⌚ **Brittleness**: property of materials that break before showing any visible deformation

# Material Examples

## Metals

☉ **Radiation modifies the stress/strain curve:** yield strength is increased slightly enlarging the elastic region, but ductility is reduced.

☉ **The material becomes more fragile...**

# Material Examples

## Air

- ⌚ Particle beams (or radiation showers) might travel in air
- ⌚ Their **interaction of the radiation with the atmosphere** generates  $O_3$
- ⌚  **$O_3$  accelerates corrosion!!!**
- ⌚ **Enclosed areas with humidity can pose problems**
- ⌚ In highly radioactive areas, humidity has to be kept as low as possible
- ⌚ **Ventilation has to be designed accordingly**

# Material Examples

## Optical Fibres

- ④ Optic fibers under irradiation tend to become opaque
  - ④ -> **radiation induced attenuation (RIA)**
- ④ The effect is reduced by limited presence of P in the fiber
- ④ **Special radiation tolerant or even 'hard' fibres exist**
- ④ The main effect is an increased attenuation factor, which may or may not affect the transmission of data (e.g, PSK)
- ④ When planning radiation testing of a fiber, it is important to analyse the **type of signal to be passed on the fiber**, to address the problem properly and measure the degradation of the relevant characteristic

# Materials to be avoided

## A few examples:

- Ⓢ PMMA (Plexiglas) < 50 kGy
- Ⓢ Butyle based Caoutchoucs < 30 kGy
- Ⓢ Perfluoro-ethylène-propylène (FEP) < 30 kGy
- Ⓢ Acetal Resins (POM) (Delrin) < 10 kGy
- Ⓢ PTFE (Teflon) < 1 kGy

Others as mentioned before

- Ⓢ PVC
- Ⓢ P-doped fibres

# Radiation Damage To Electronics (R2E)

*“Failures of electronics caused by radiation are not necessarily a problem!”*

*“It’s their total number and impact on machine operation and system lifetimes!”*

# Exposed Equipment

- @ Usually numerous **systems** affected  
(powering, control, cooling, monitoring, etc.)
- @ Several can be critical for **beam operation**
- @ Some to be located in “**high-radiation**” areas

## A few (simple) numbers on the example of the LHC

- @ ~20 different **exposed system**
- @ From a few to a **few thousand units** each
- @ number of parts per (per system)  
range **from a few to a few hundred**

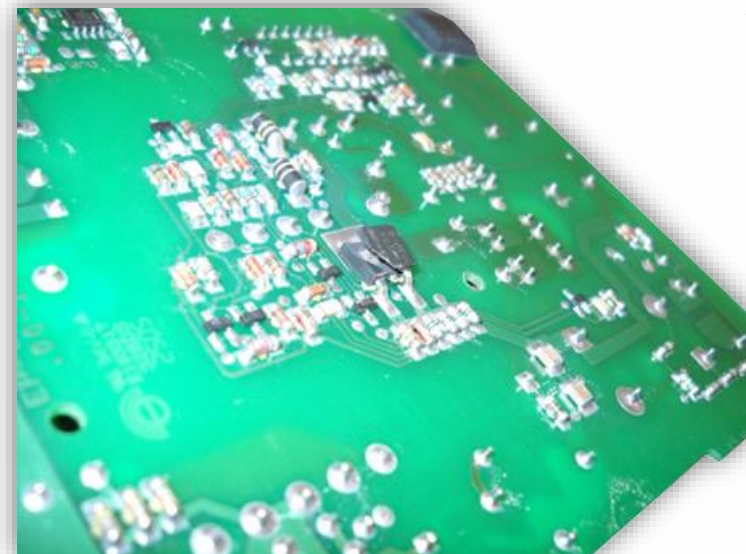

$$N_{failures} = \int \phi(x) \sigma(x) dx \times N_{devices} \sim \Phi(x > X) \sigma \times N_{devices}$$

- @ **Reliability = low number of failures/short down-times!**

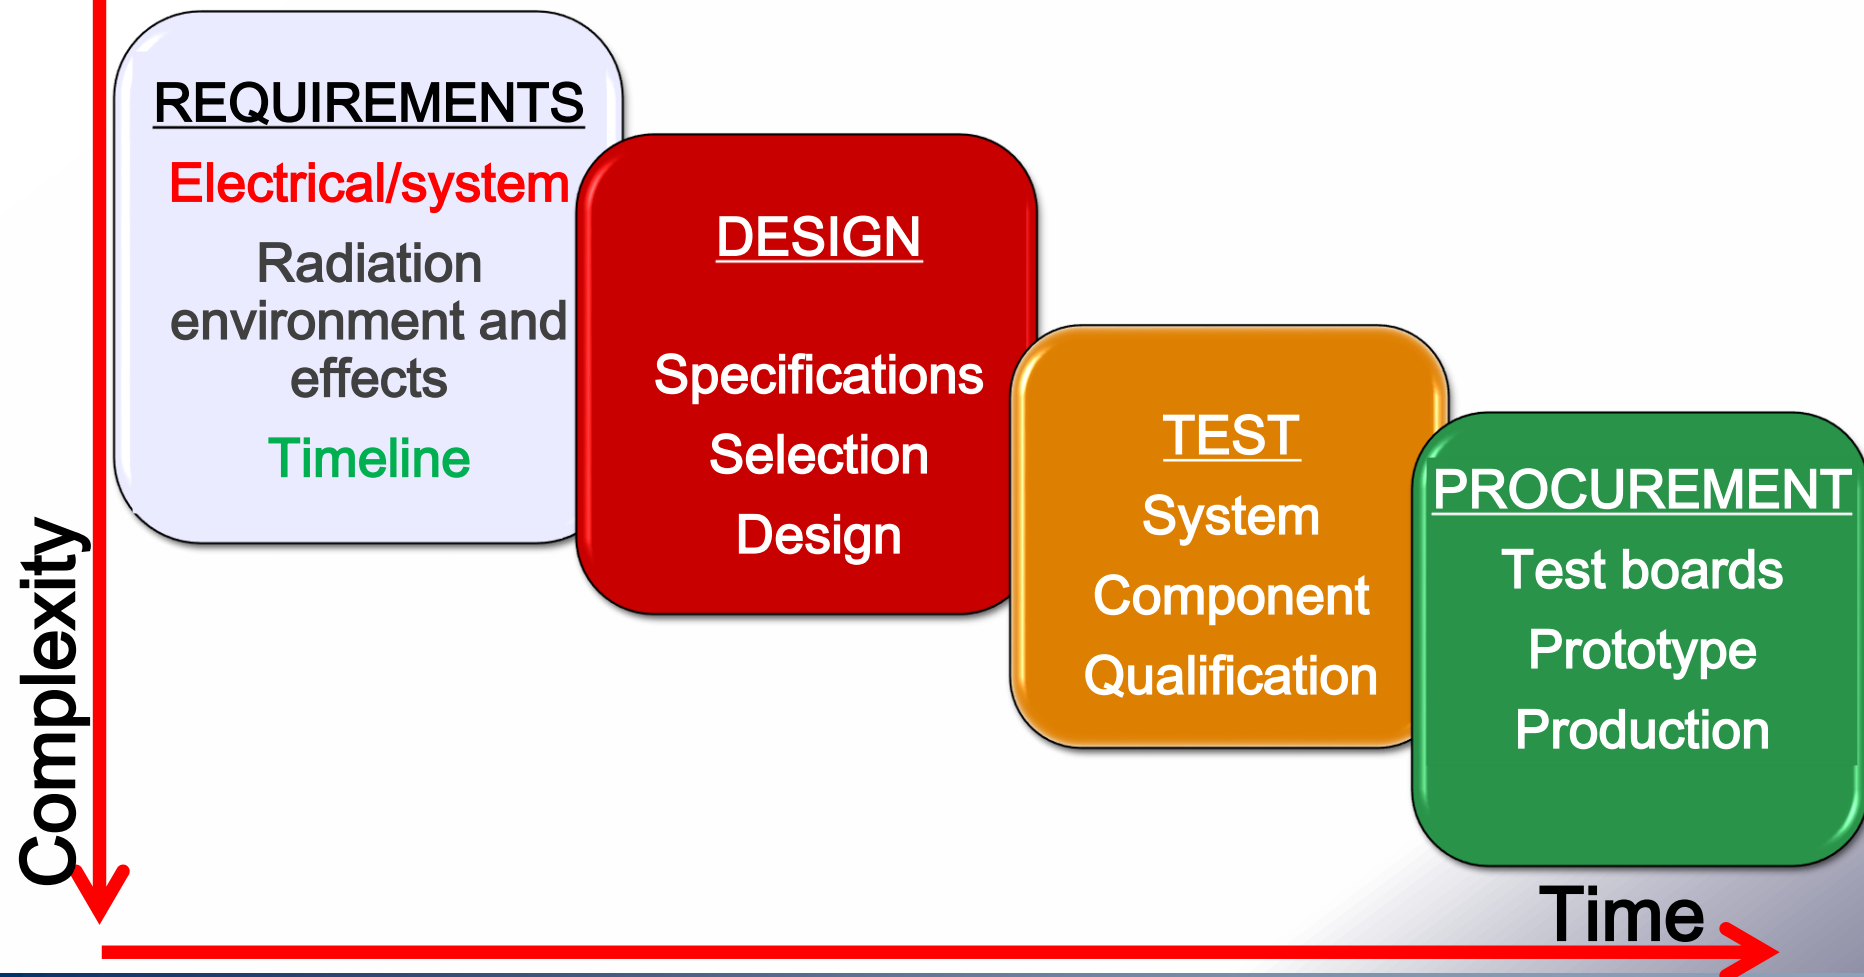

## SEE: Power-Converter (LHC\_RR)

⇒ Premature Beam Dump  
& LHC Downtime

- ⌚ Radiation tests is a phase of a new development
- ⌚ Rad constraints to be considered from day-0

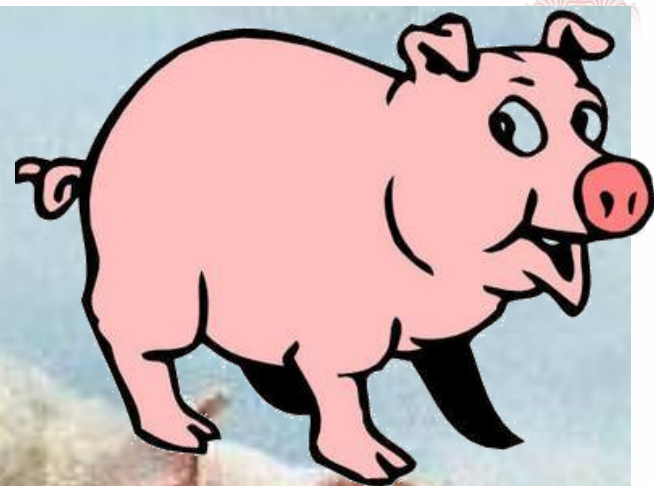

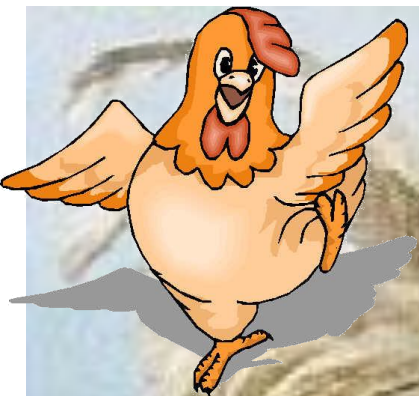

RELOCATION

SHIELDING

# Mitigation Measures

RAD-TOL DESIGN  
& TESTING

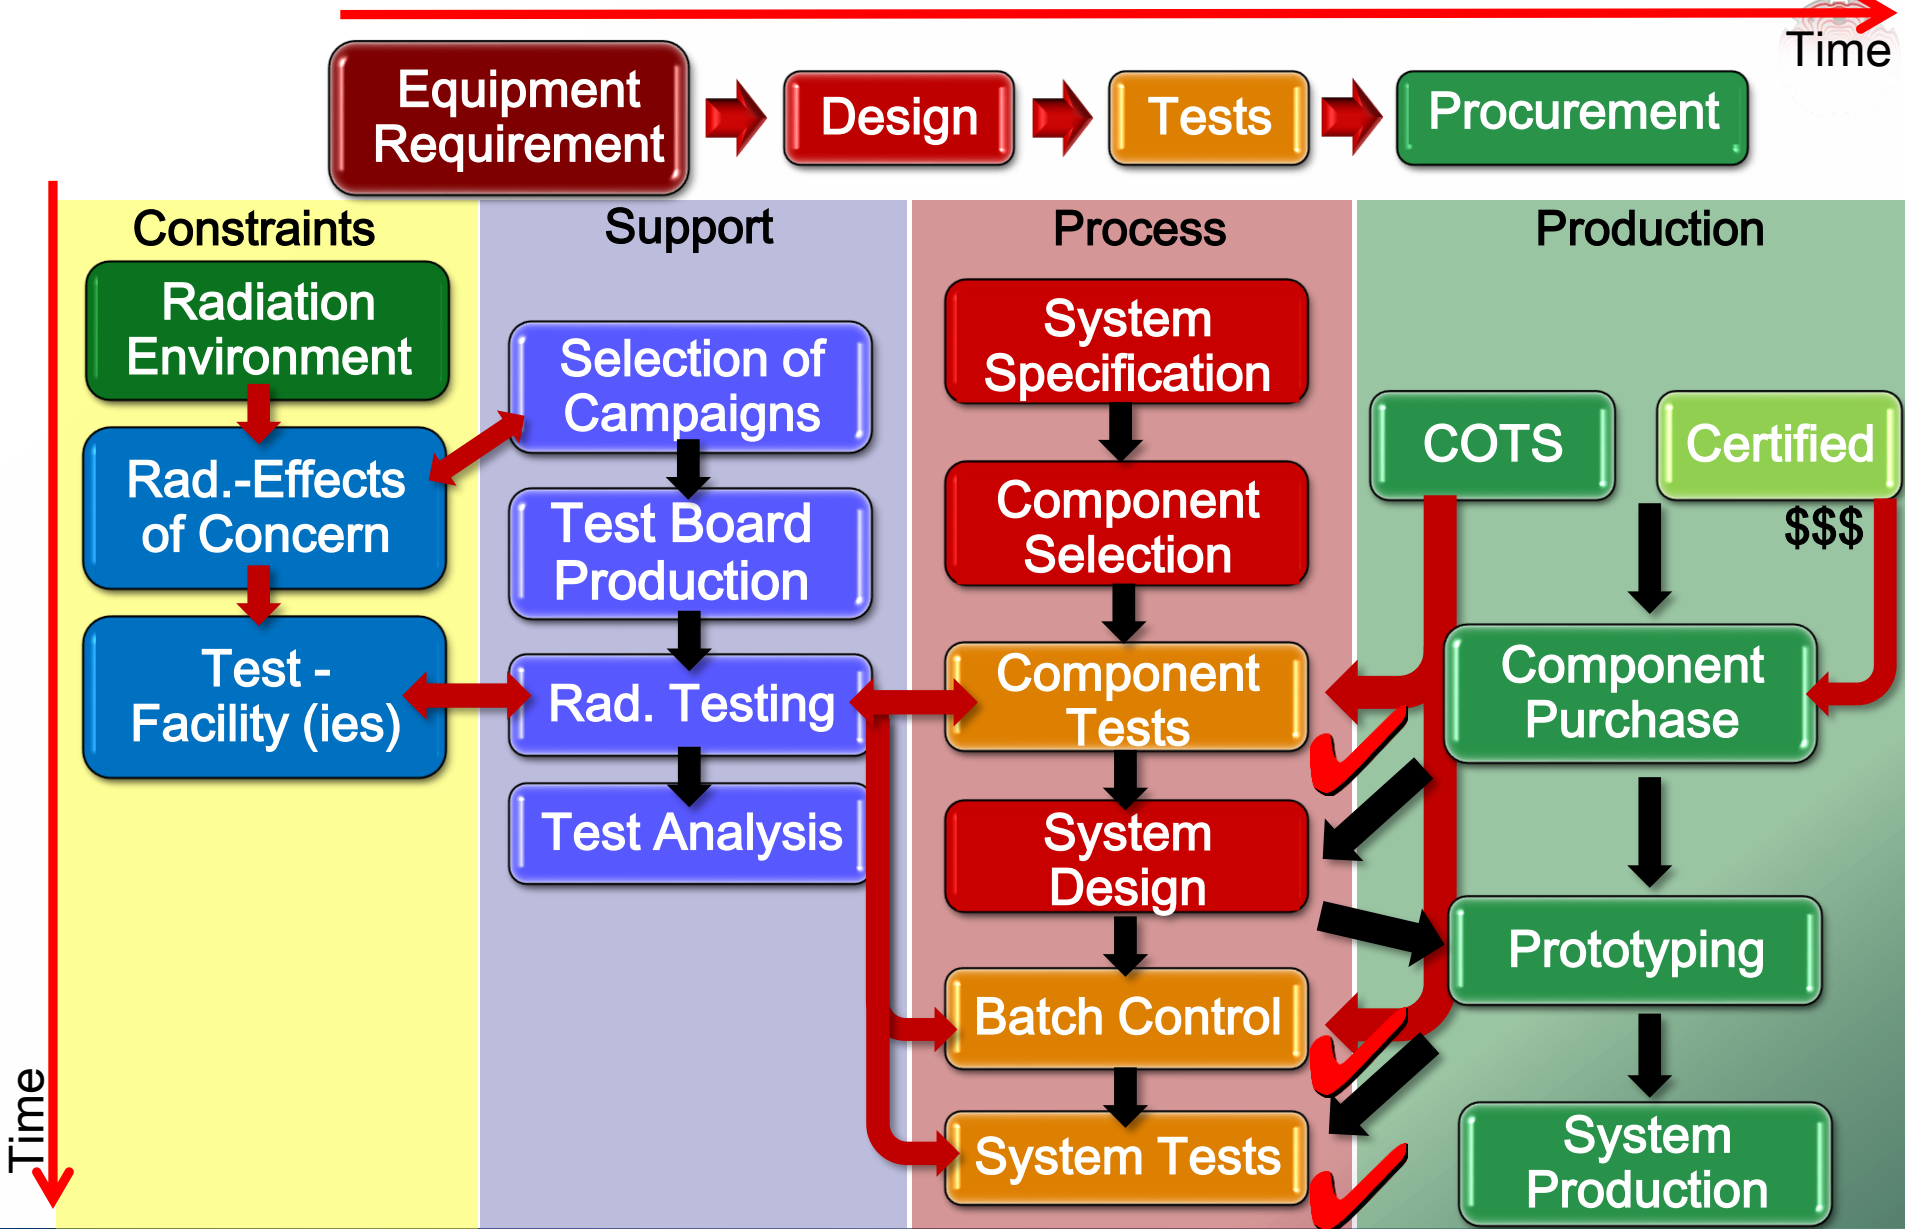

~~CIVIL  
ENGINEERING~~

**Certainty: it's not 'easy'...**

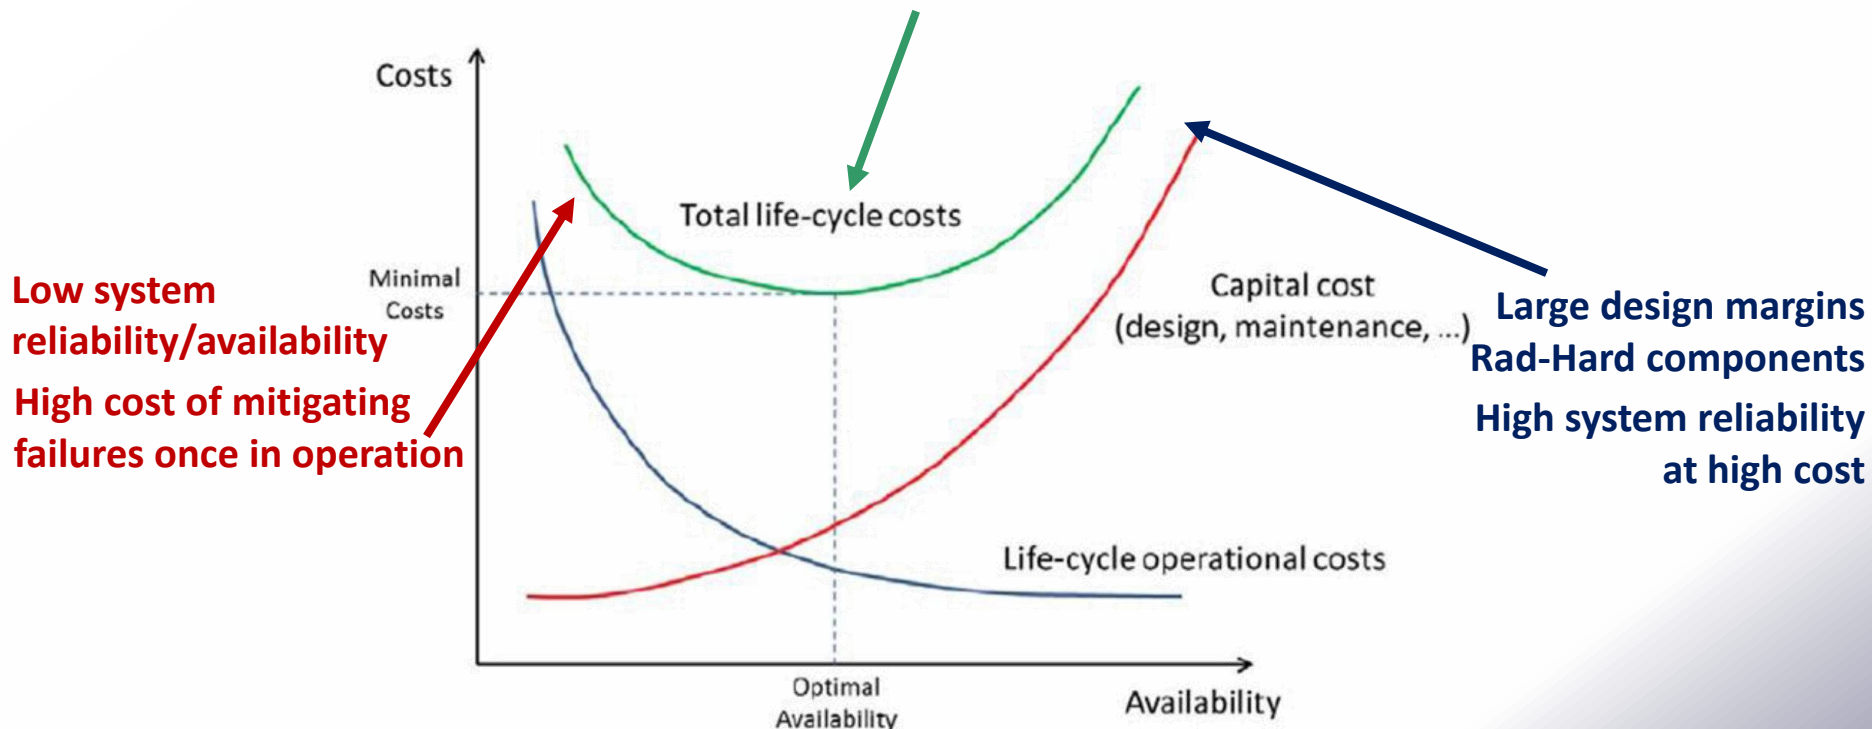

# A (Rough) Map to Rad-Tol

## System Availability vs. Development Cost

**Optimum** between **reliability/availability** for operations  
and **design/qualification costs**

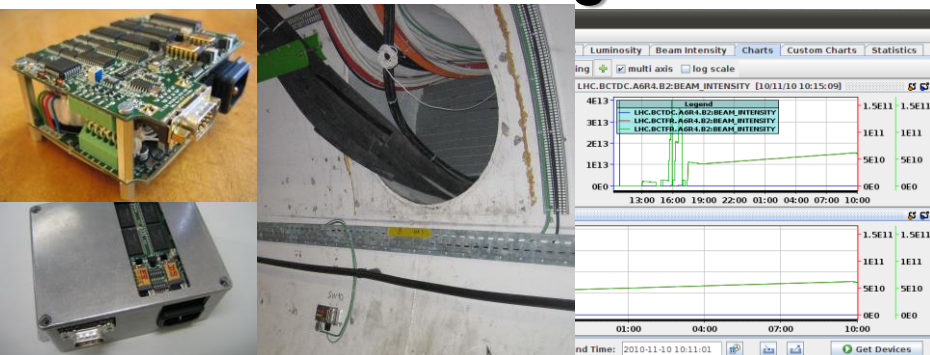

**Optimum depends on:** radiation levels, criticality for operations, system failure rate  
Combining **top-down** (from system to component) and **bottom-up** (discrete component qualification)

# Conclusions

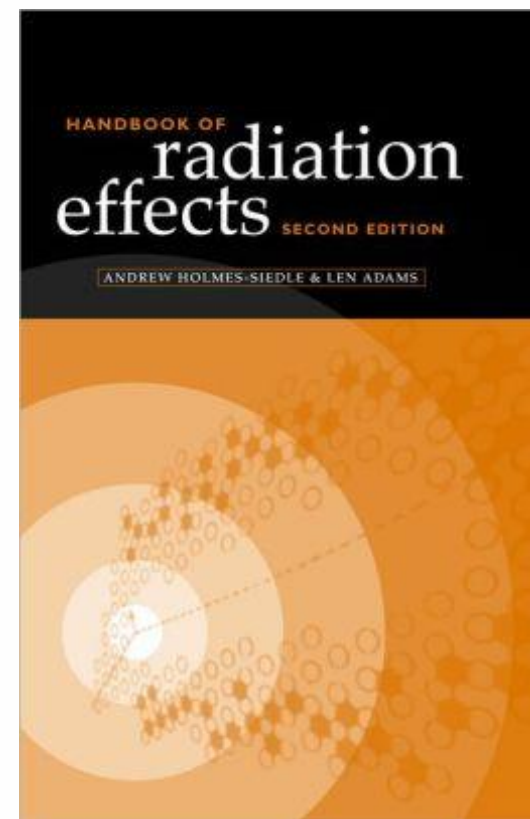

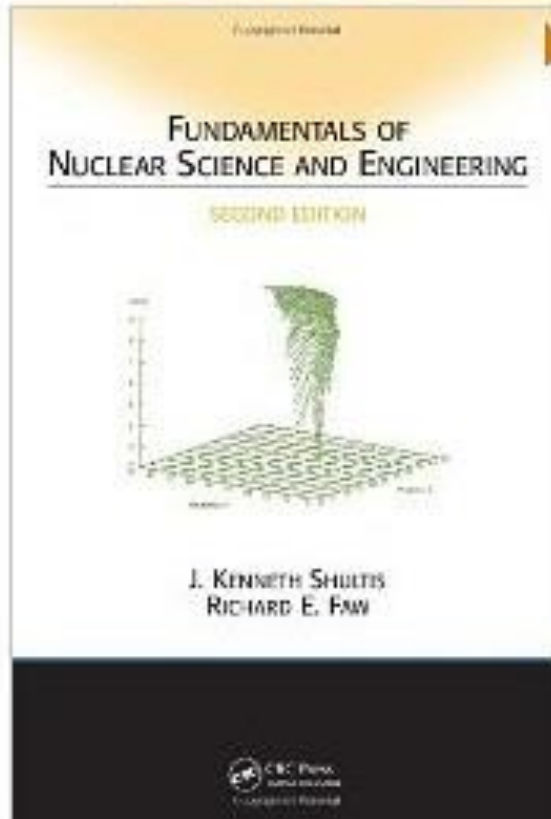

- ⊗ **Radiation provokes a lot of undesired effect**
  - ⊗ You cannot avoid them!!!
  - ⊗ The only rule is to anticipate damage
  - ⊗ ALARA is the magic word: and not only involves preparation of interventions, but also:
    - ⊗ selection of materials, components, designs
    - ⊗ mitigation measures
- ⊗ **Think first & carefully of what you use where!**
  - ⊗ Ask yourself the question:
    - ⊗ is it really worth to do what I am doing?
    - ⊗ and in the way I am going to do it?
- ⊗ **Don't hesitate asking**
  - ⊗ Lot's of expertise exists, sometimes close-by!

- ❑ A Complex Programmable Logic Controller (CPLD) was tested using **60 MeV protons**
- ❑ **No SEEs** were **observed** for the **three devices** tested before these started failing due to total ionizing dose effects (cumulative) after 120 Gy.
- ❑ The component was then exposed to high energy particle radiation at an **LHC-environment**. **Permanent destruction** of the part occurred in the **early stage** of the test.
- ❑ Importance of **testing** in the actual **operation environment** (not always feasible in a systematic way) and of being able to **model/predict** the **error rate** (energy dependence knowledge, for example)

# Energy Dependence

Above  $\sim 100$  MeV, the total hadron-Silicon inelastic cross section is saturated, however:

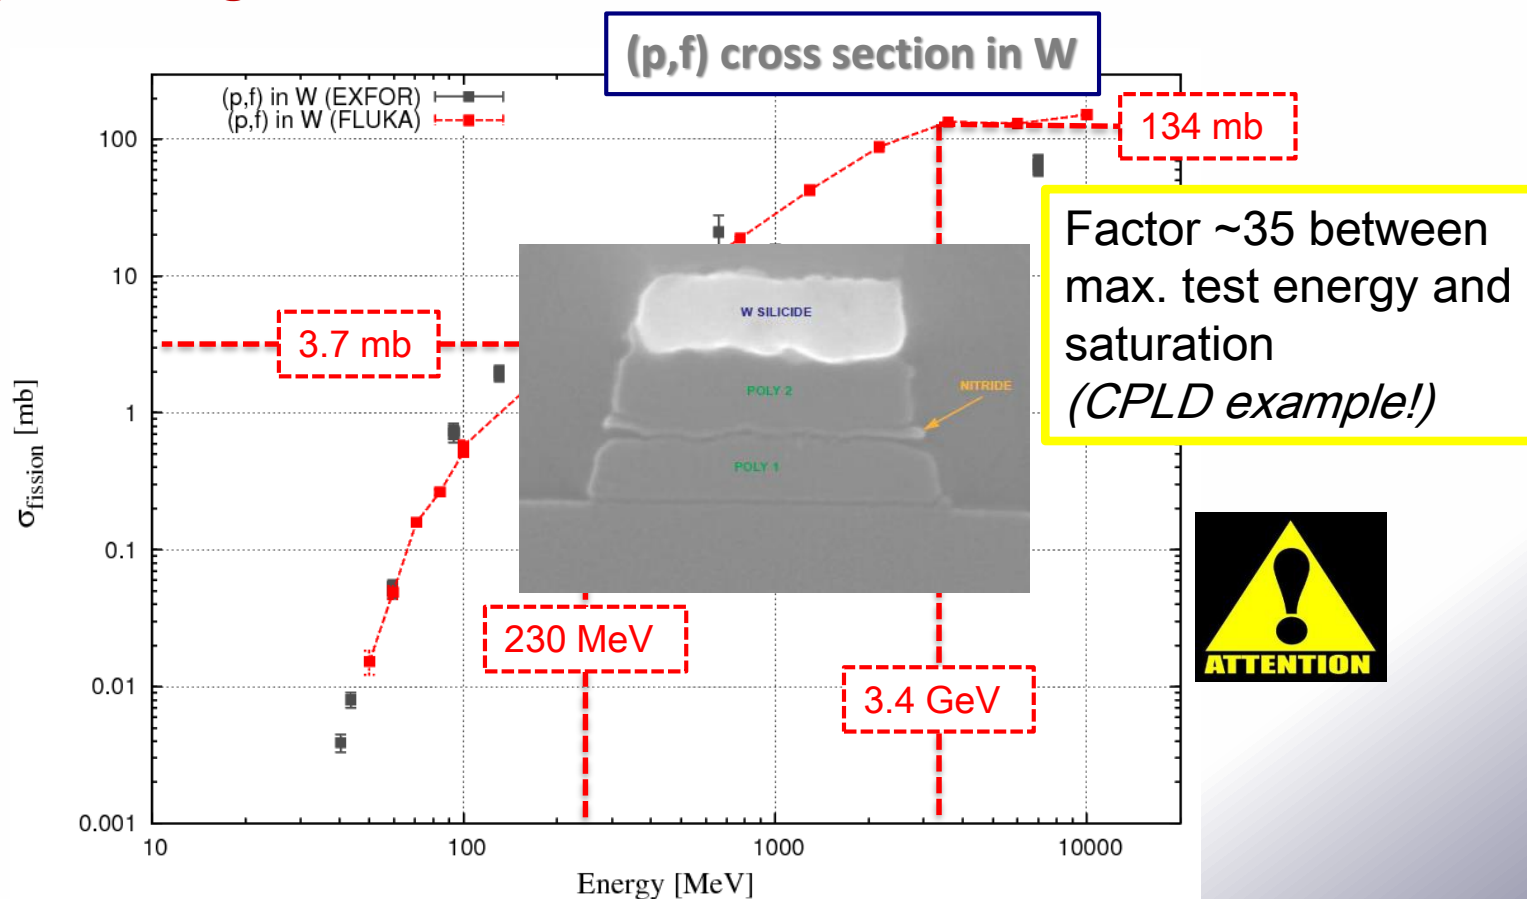

- more light, long-ranged fragments are produced
- and they are produced with larger energies (and therefore ranges)

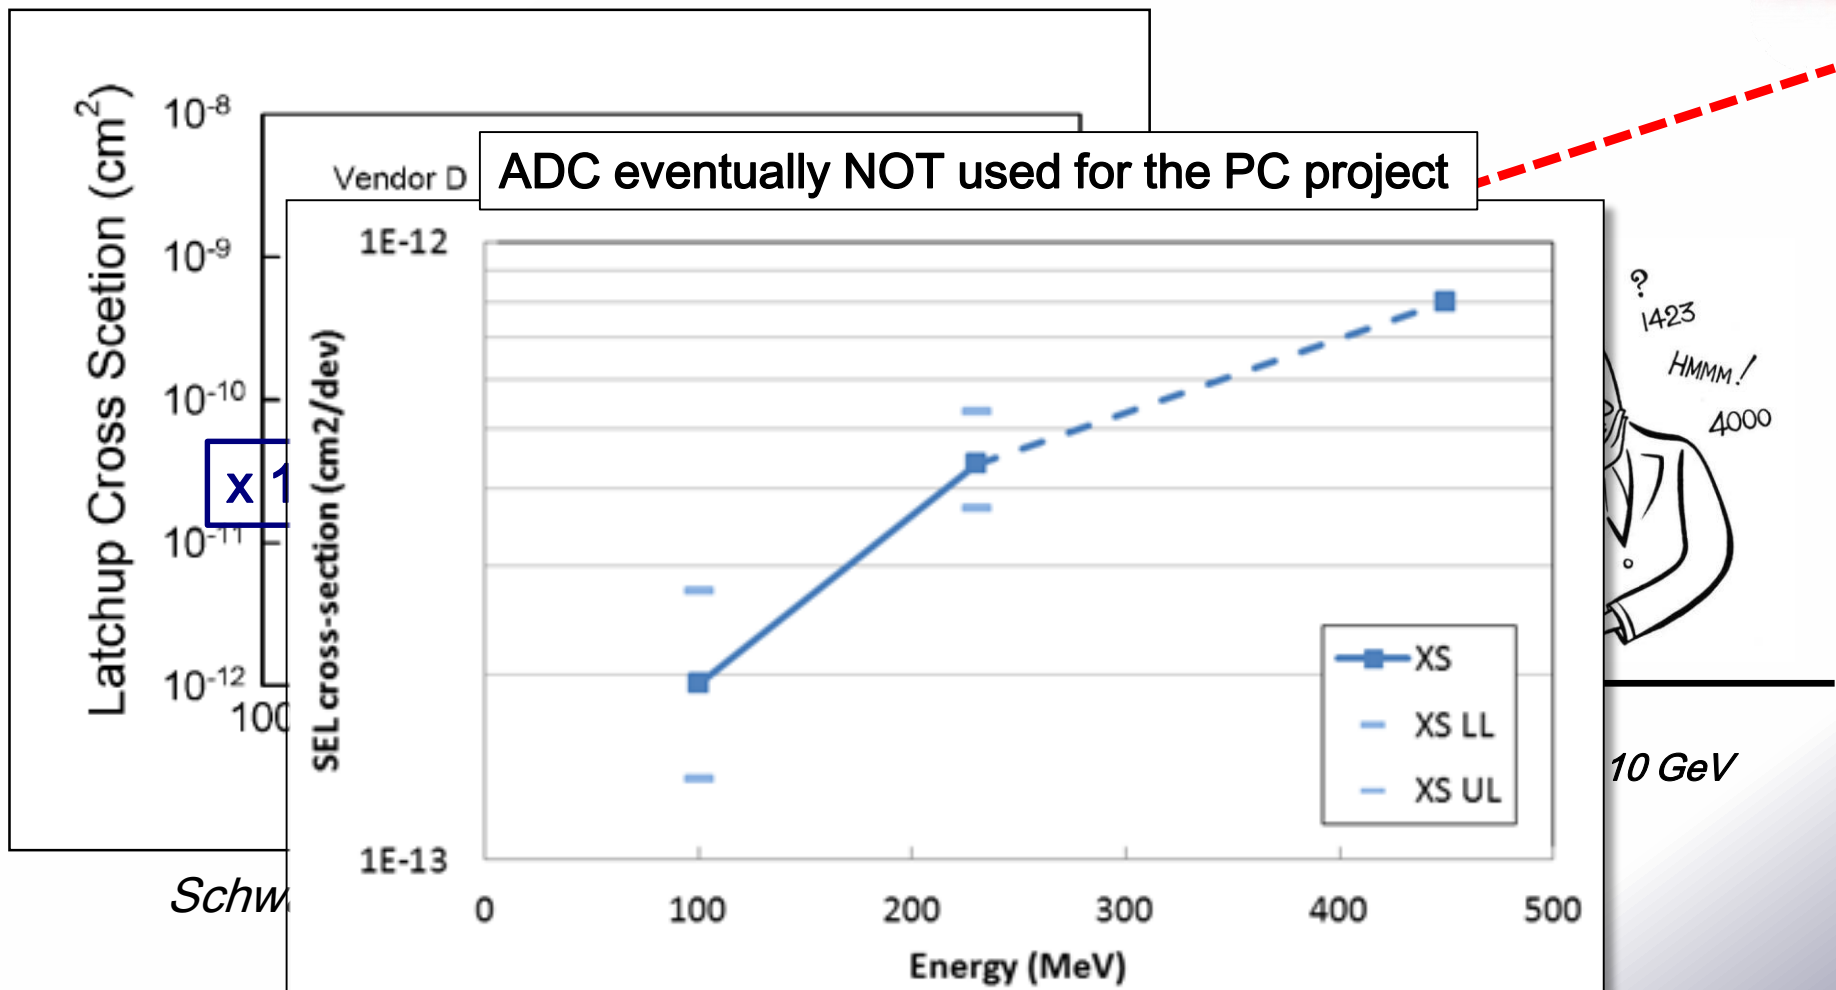

© R. G. Alia

# SEL & Fission: Energy Dependence

- ⊗ **High-Z materials** (namely **tungsten**) are often used in the interconnection layers of the memories, **near the sensitive volumes**
- ⊗ Energetic hadrons can induce **fission** in these materials, producing very **high-LET fragments** that can **dominate the SEE cross section**

# SEL: Energy Dependence

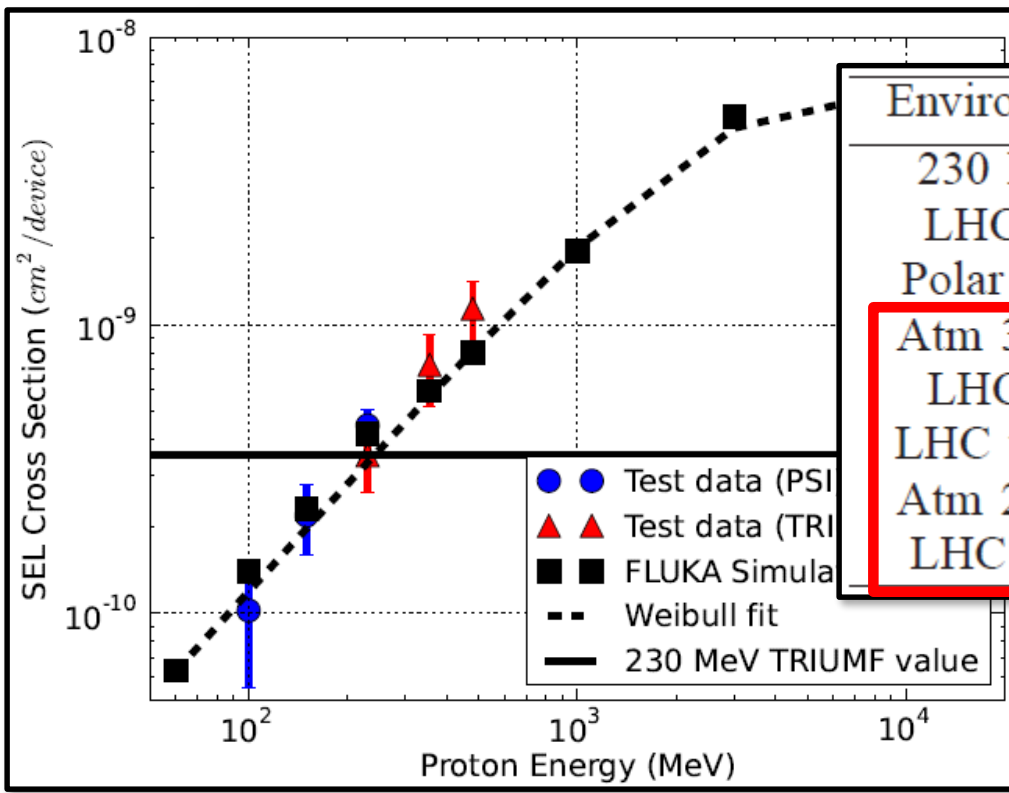

*R. Garcia-Alia (IES & CERN Thesis 2012-2014)*

# SEL: Energy Dependence

- Important possible dependency for high-energies
- Strong impact on various radiation environments

Compared to 100MeV

Environment	Case I	Case II	Case III
230 MeV	1.8	2.8	3.4 (1.0)
LHC HS	0.7	0.8	0.9

of W

# Why do we (at CERN) care about SEEs?

- ❑ **Commercial components** used in systems operating in or near the **LHC-tunnel**  
(power converters, cryogenics, QPS system...)

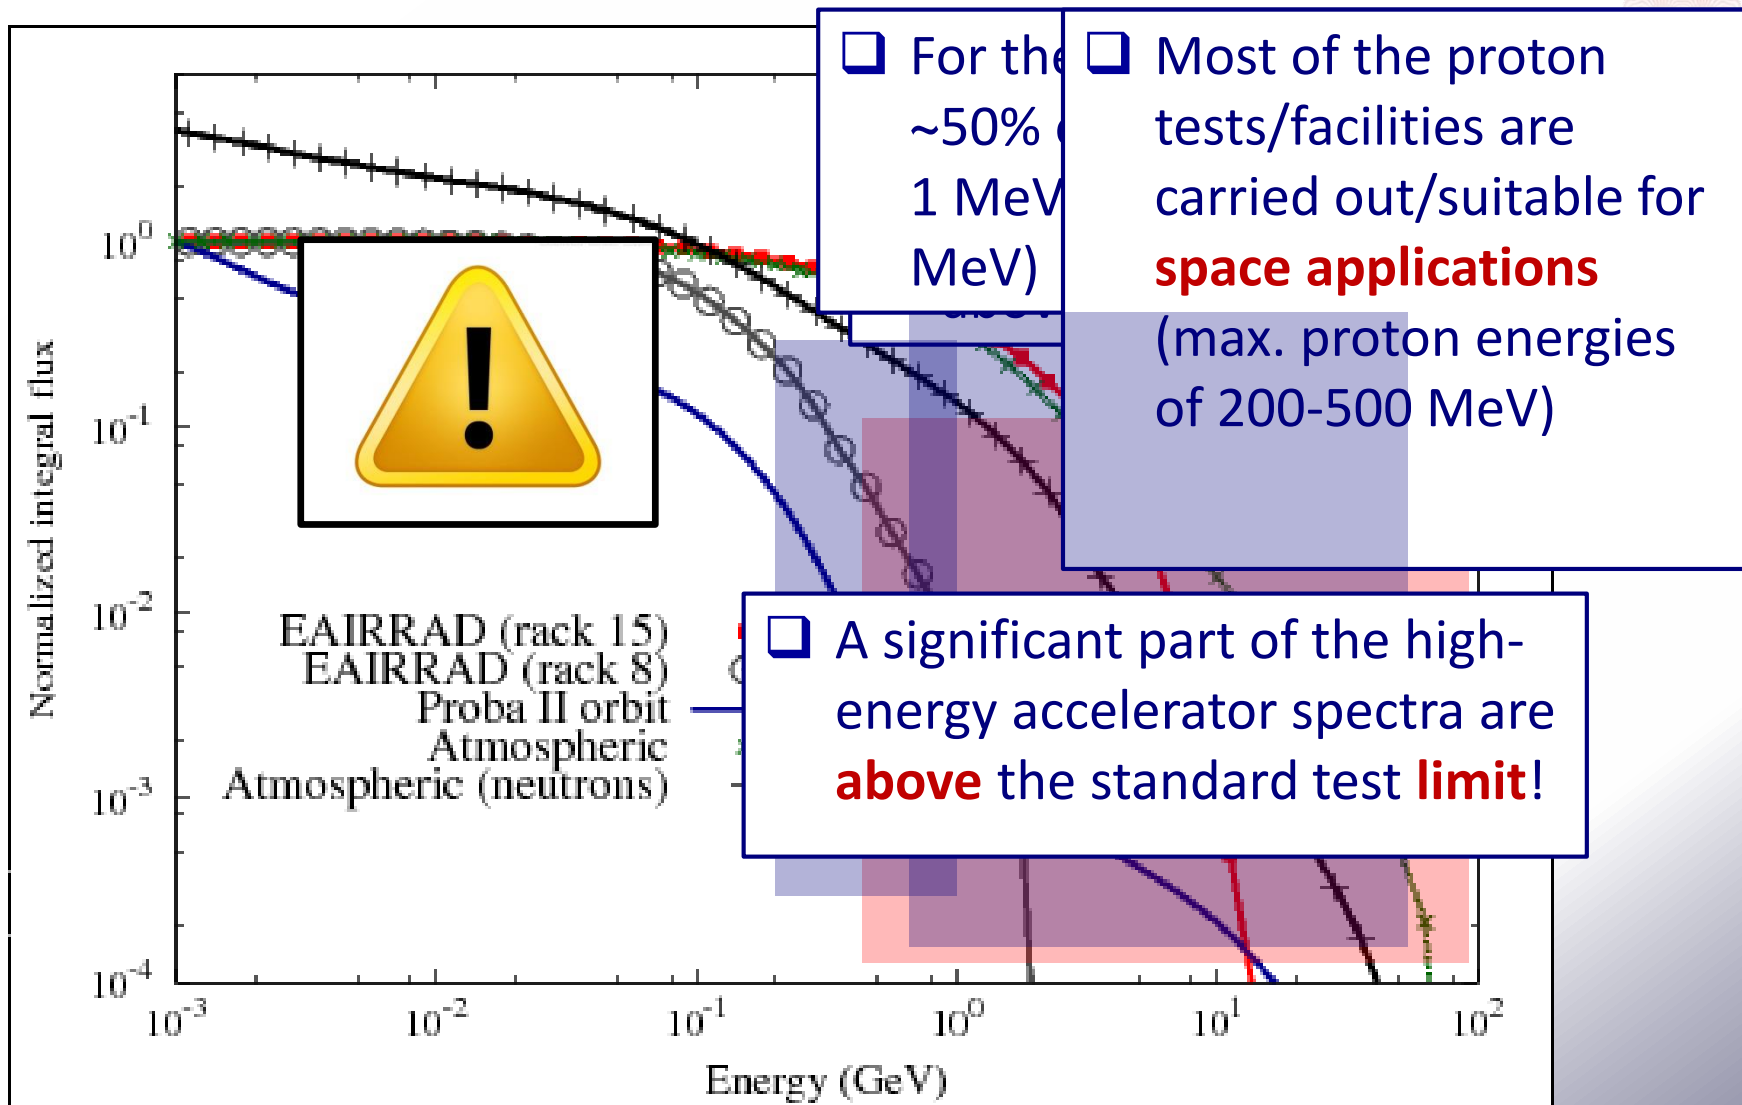

- ❑ **Intense radiation fields** at the locations of operation

- ❑ **SEEs, TID and DD** in components and systems **affect the operation of the accelerator** (beam dump, etc.)
- ❑ Need to **test, monitor, mitigate** and **predict** (R2E project).

## Hard Failure

An error induced by faulty device operation. DATA is lost AND data/function is lost and can no longer operate at that location.

## Soft Failure

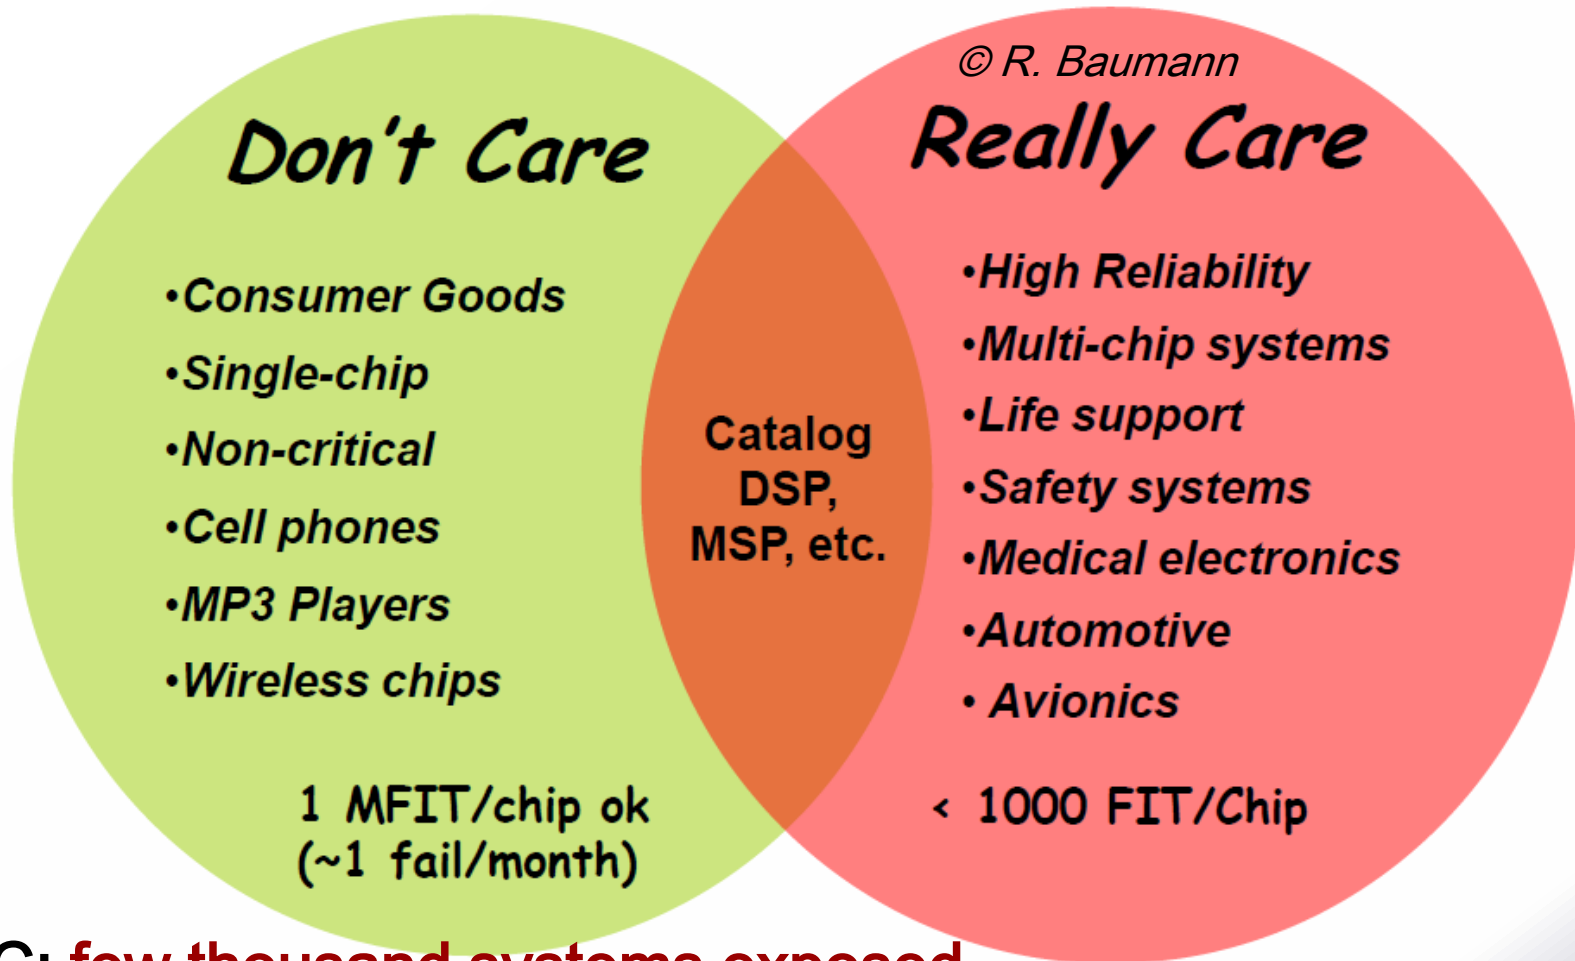

An event corrupting only the DATA stored in a device. The device itself is not damaged and functionality is restored when new data is written.

$$1 \text{ FIT} = \frac{1 \text{ failure}}{10^9 \text{ dev} - \text{hrs.}}$$

*1 FIT is 1 failure in 114,155 years!*

*or 100,000 FIT is ~ 1 failure/year*

© R. Baumann

**LHC: few thousand systems exposed**

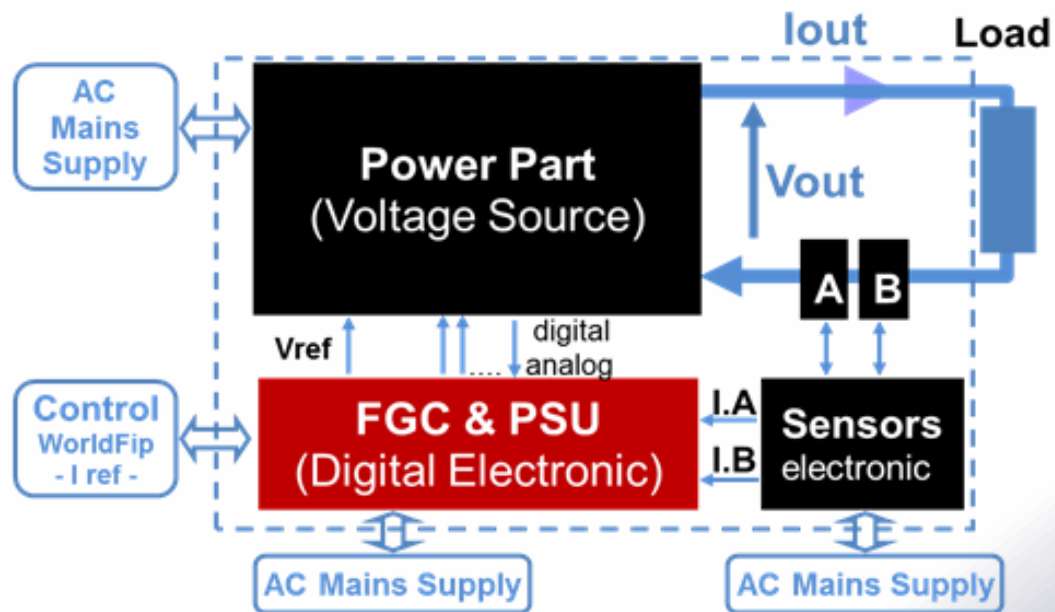

**Aim: less than one radiation induced failure per operational week**

**Reliability in FIT: -> aiming for about 1 FIT/SYSTEM!**

**Per Chip? (better don't do it)**

## ❑ Driving the magnets in the accelerator

- ❑ Partly high-precision requirements
- ❑ Large number of internal components (high power, low voltage, control, etc.)
- ❑ Very high number of exposed units

## ❑ Minimize the number of converter types:

- ❑ Only the LHC60A-08V was specified for a radioactive environment !
- ❑ 3 other converter types are part now of the radioactive sensitive areas!

Quartz	1	2	2	1
Opto			4	
Transistor	7	20	27	
IC	22	5	26	30
Total	38	46	118	40

**0.5M semiconductors/2.3M components**

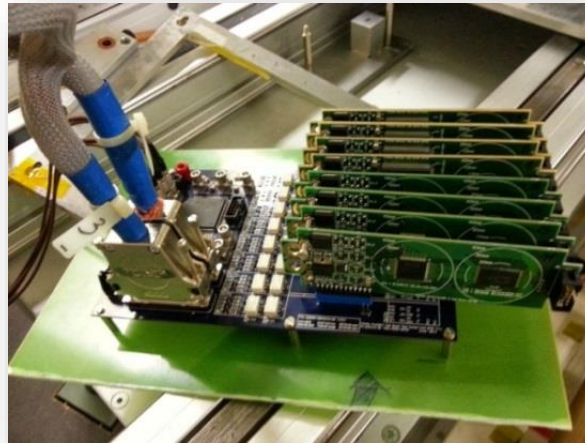

**New testing infrastructure to qualify components under radiation**  
**Real-time SEE & TID tests, & multiple components**

**-> S. Uznanski: NSREC Talk: (SEE, Devices and ICs) D--4**

**Prototype**

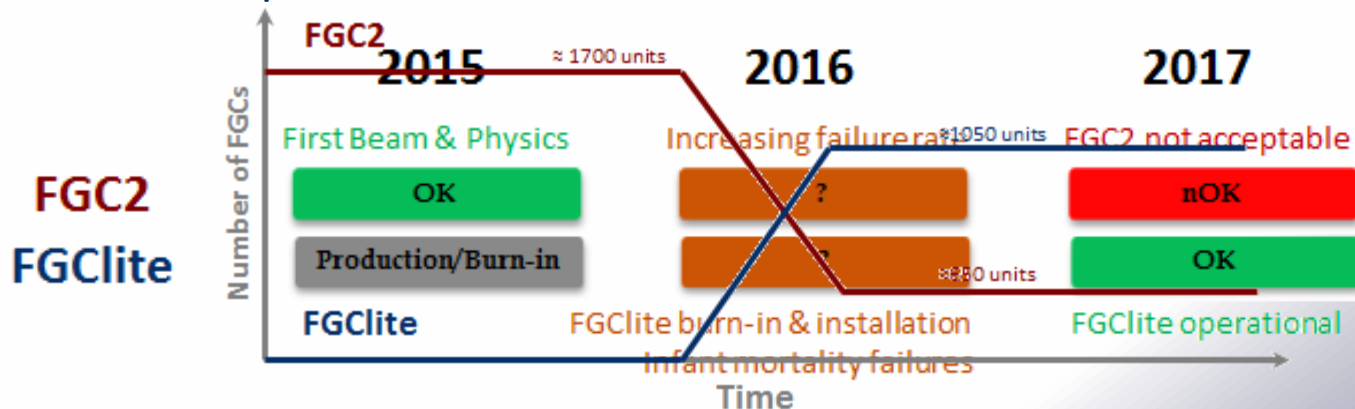

**FPGA Type Tester**

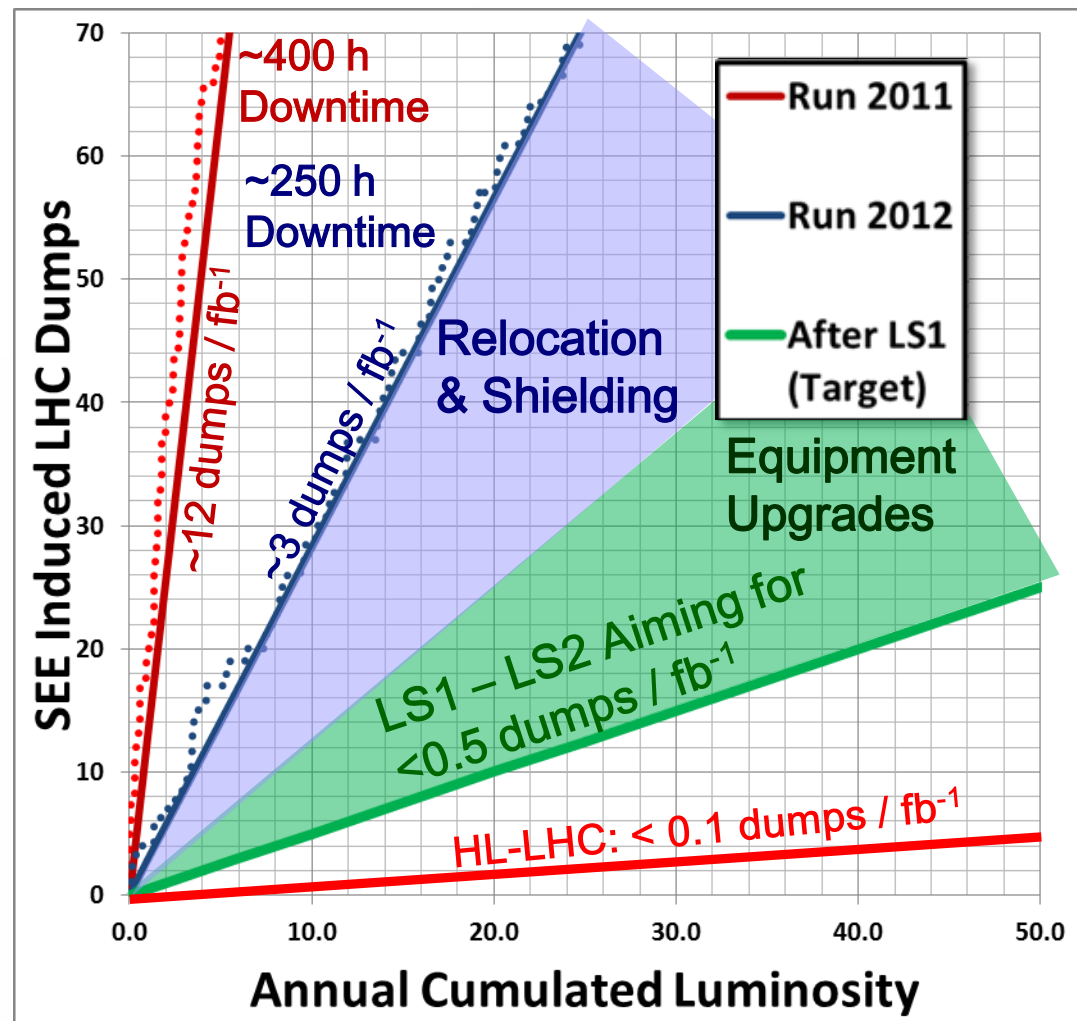

**ADC Type Tester**

- @ **2013** – hardware design, prototype available & component type testing
- @ **Q3/2014** – 10 fully validated FGClite proof-of-concept modules
- @ **Q3/2014** – start of component batch testing using CHARM (PS East Area)
- @ **Q2/2015** – Series production

## R2E SEE Failure Analysis

### 2008-2011

- Analyze and mitigate all safety relevant cases and limit global impact

### 2011-2012

- Focus on long downtimes and shielding

### LS1 (2013/2014)

- Final relocation and shielding

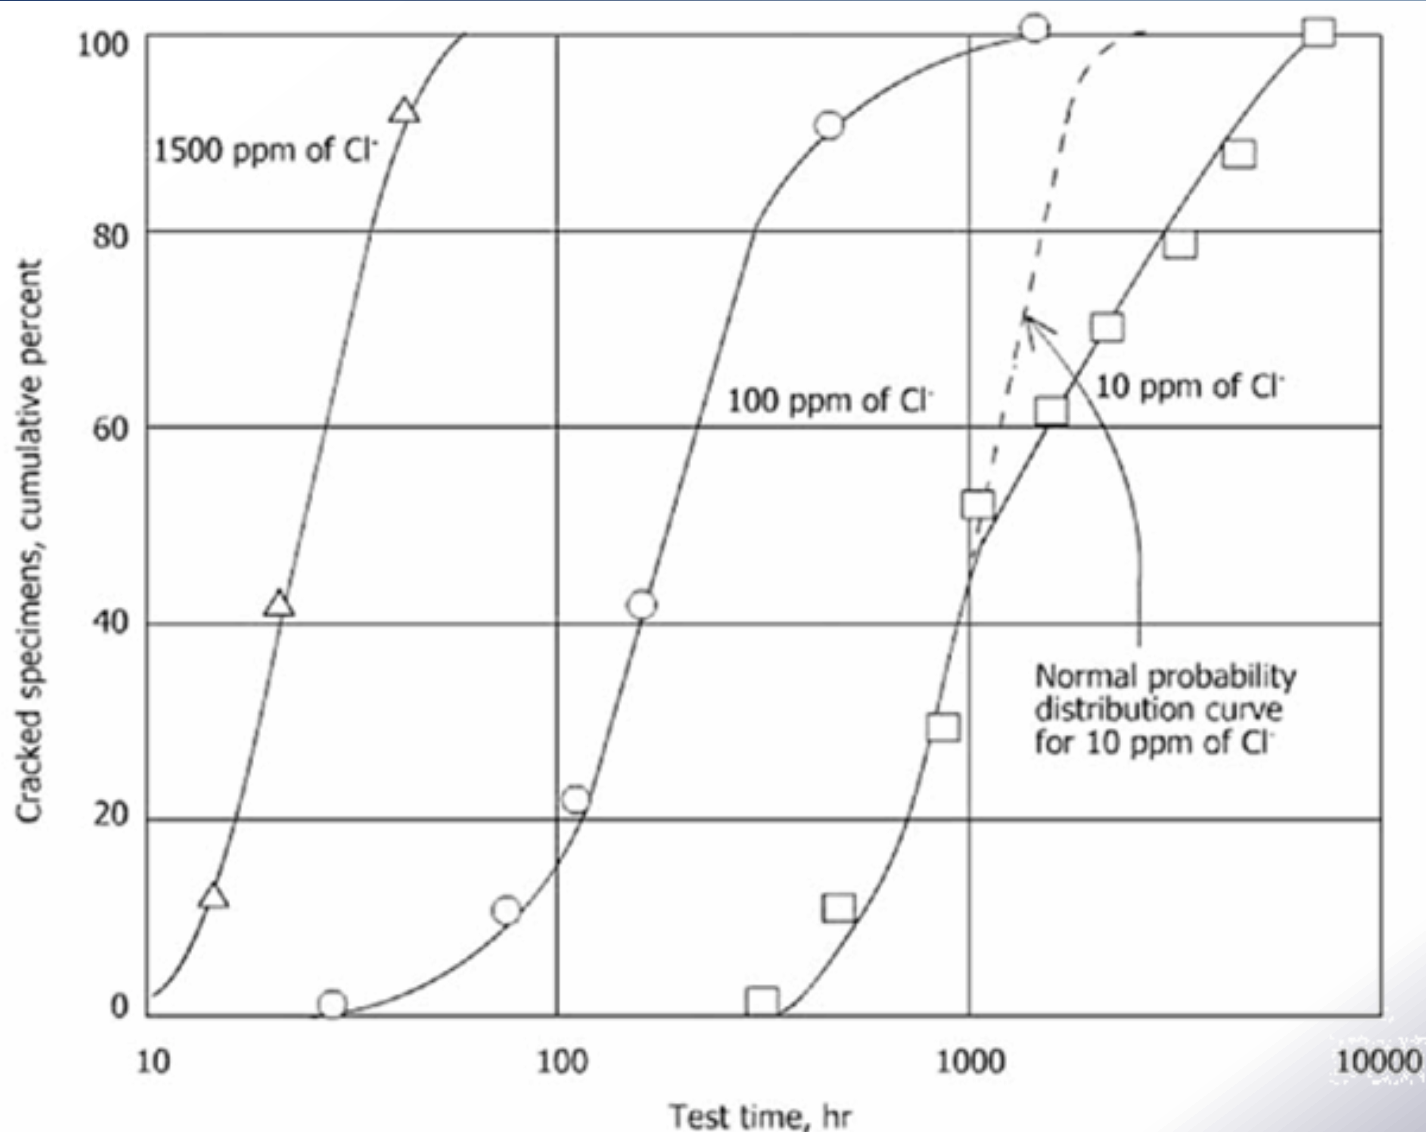

### LS1-LS2 (2015-2018)

- Tunnel equipment and power converters

### -> LS3-HL-LHC

- Tunnel Equipment (Injectors + LHC) + RRs

# Chlorine - Corrosion

*Ahmad Zaki, Principles of Corrosion Engineering and Corrosion Control, Elsevier*
